Introduction

Defining the severity of stenosis by duplex is only half of the carotid story. There's more than just the PSV and EDV.

Plaque Characterization

Plaque morphology includes:

- “Surface” (smooth vs. irregular)
- “Structure” (heterogeneous, echolucent, ulcerated, hemorrhagic, homogeneous, or calcified)
- Combination of “surface” and “structure” defines plaque stability
- One or more of these qualities increases the patient’s risk for ischemic stroke

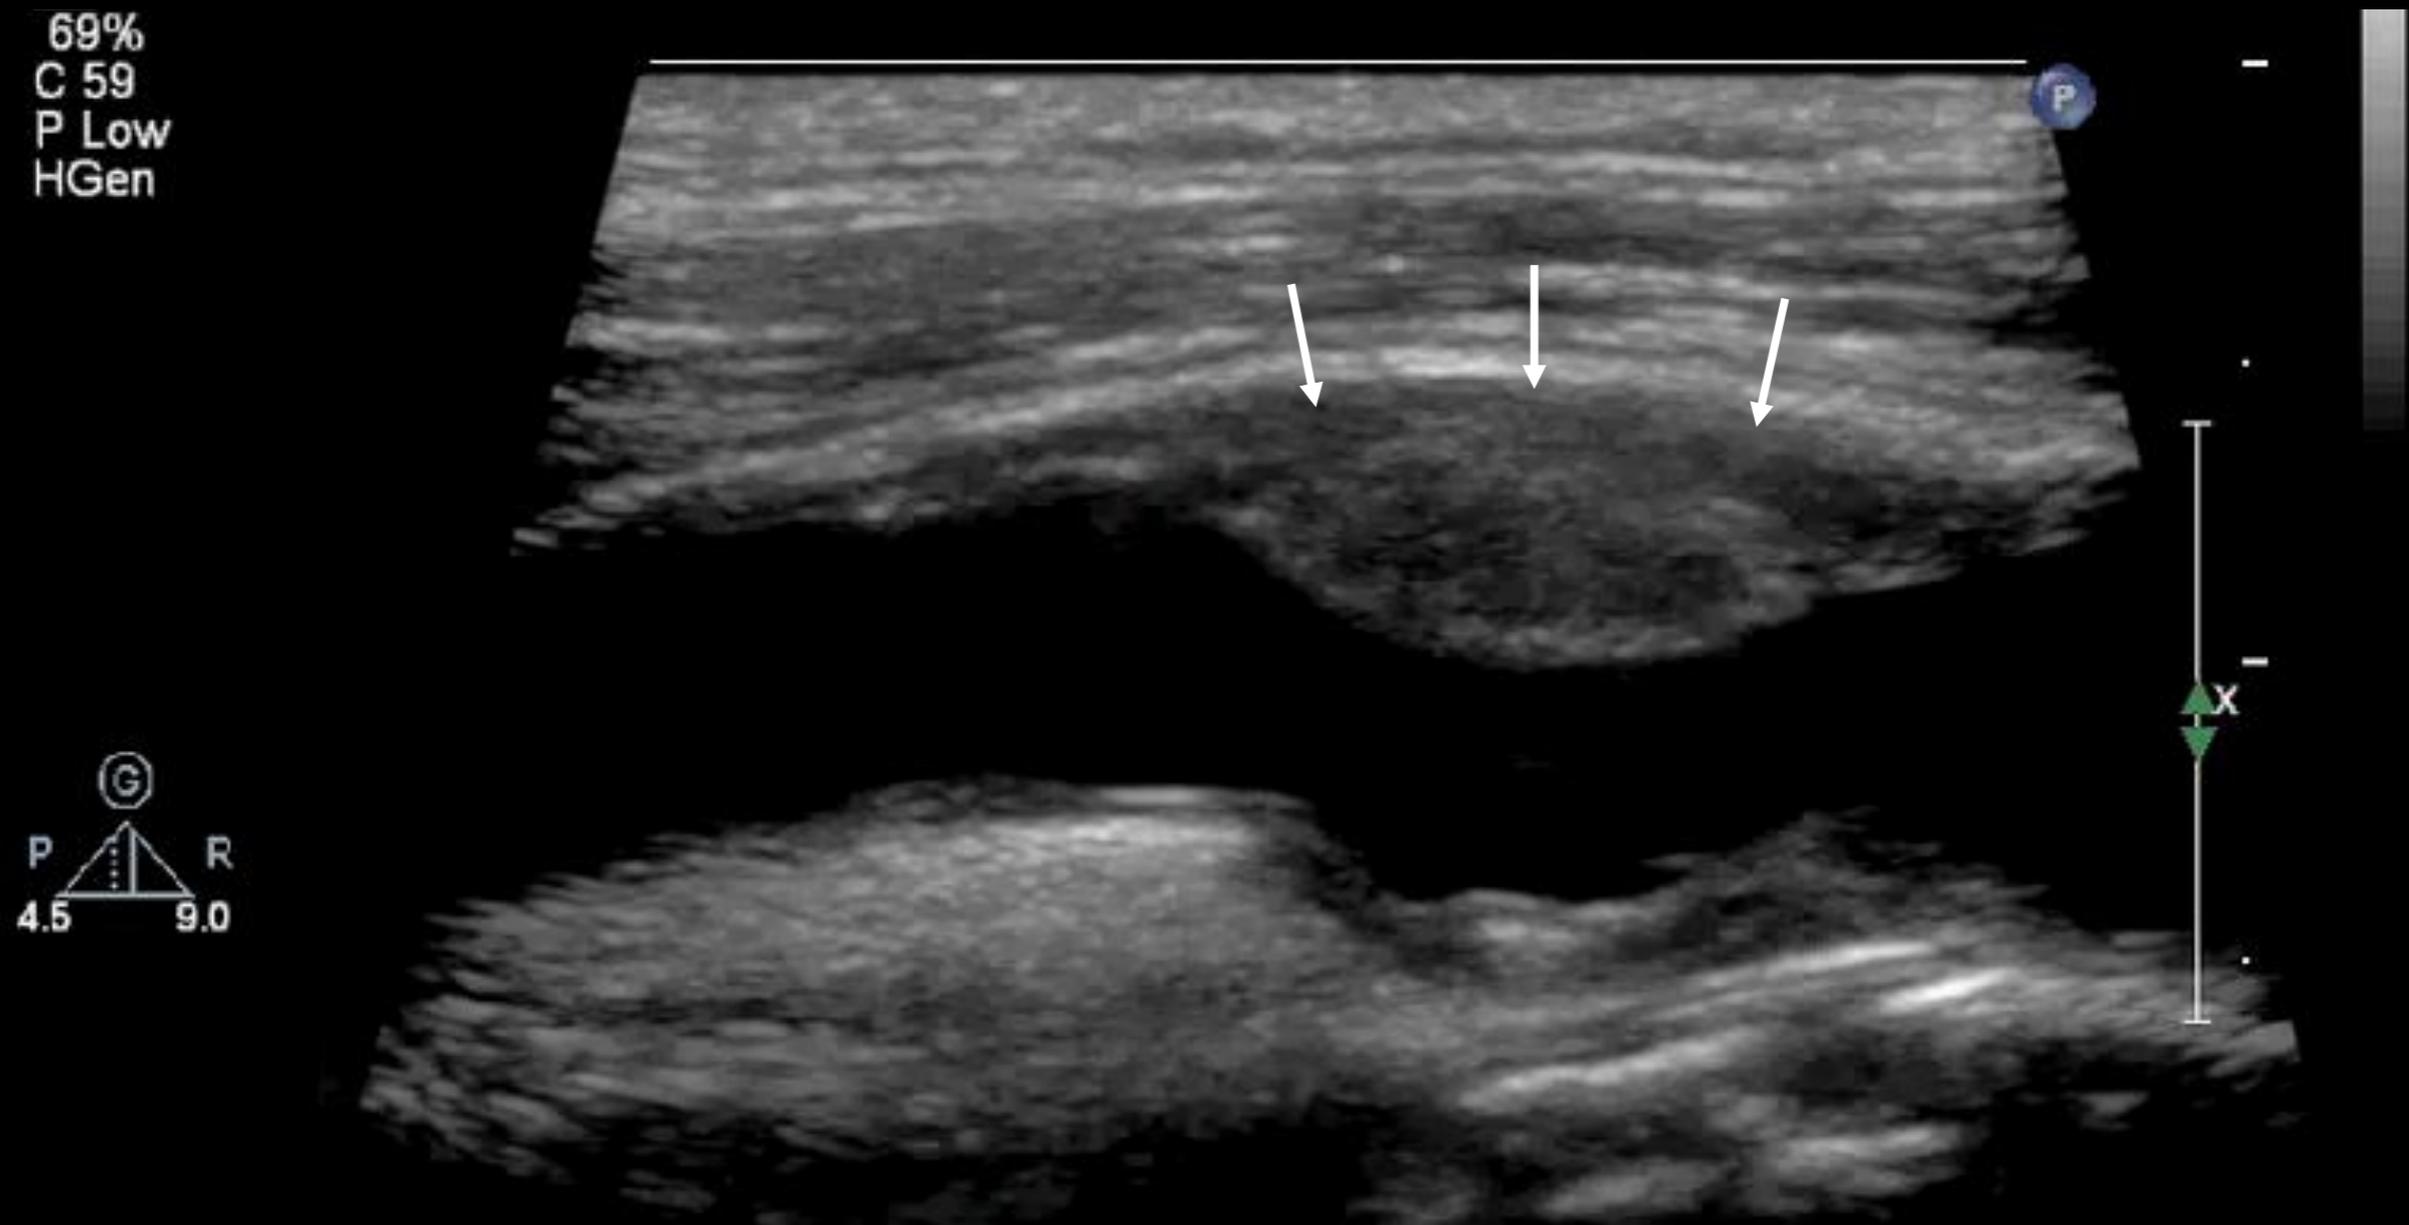

Heterogenous Plaque

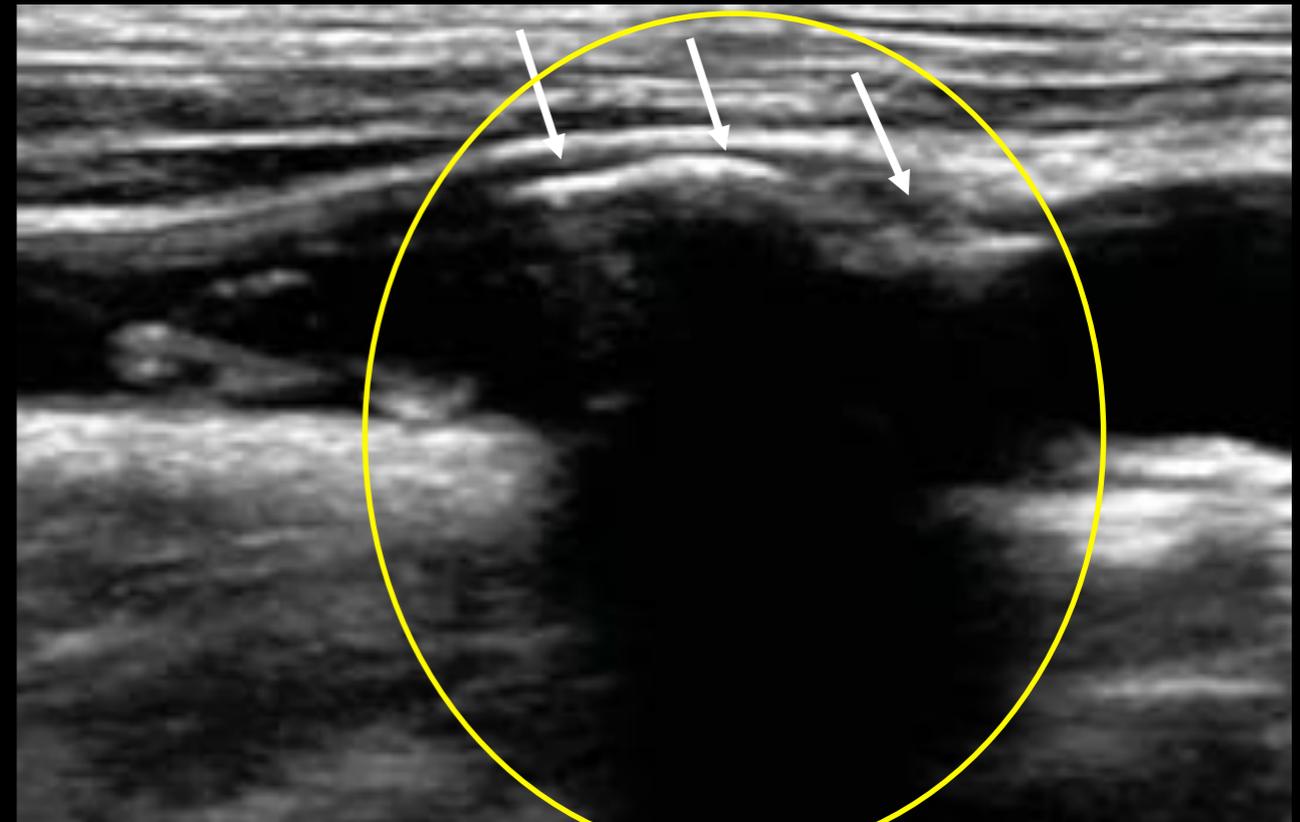

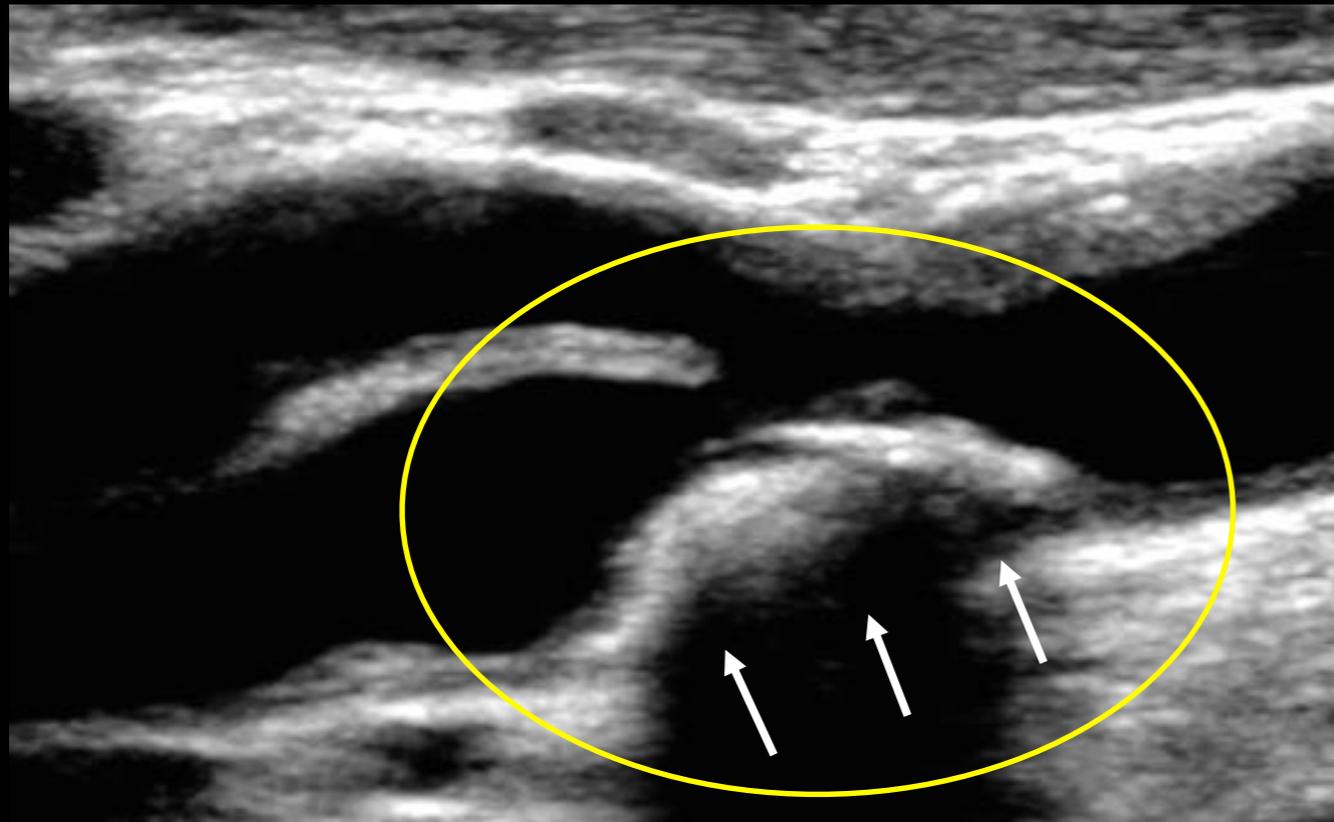

Ulcerated Plaque

Homogeneous Plaque

Uniform echotexture and smooth surface

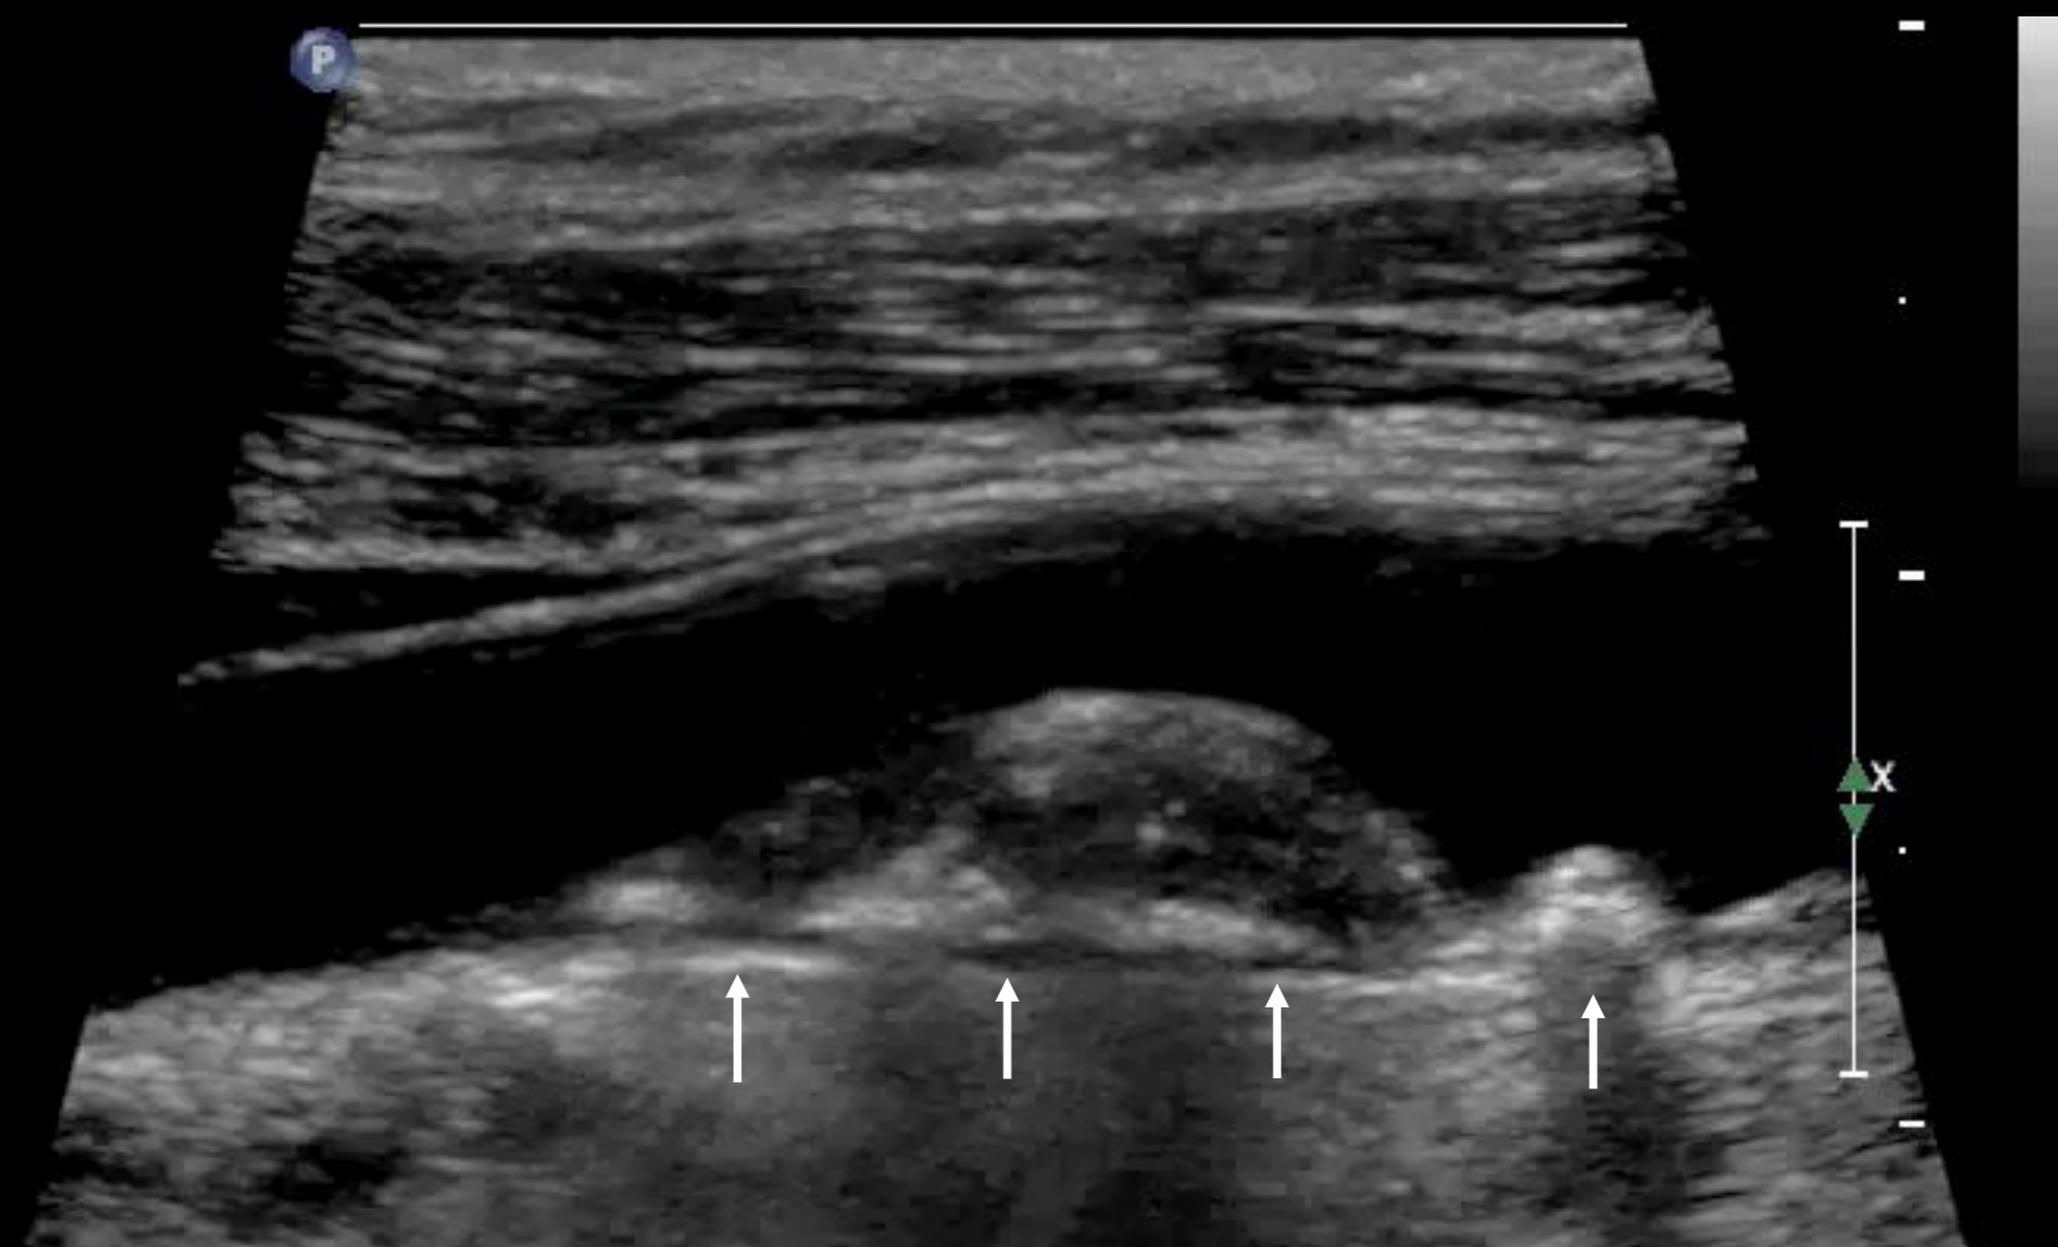

Calcified Plaque with Acoustic Shadowing

Heterogeneous Plaque

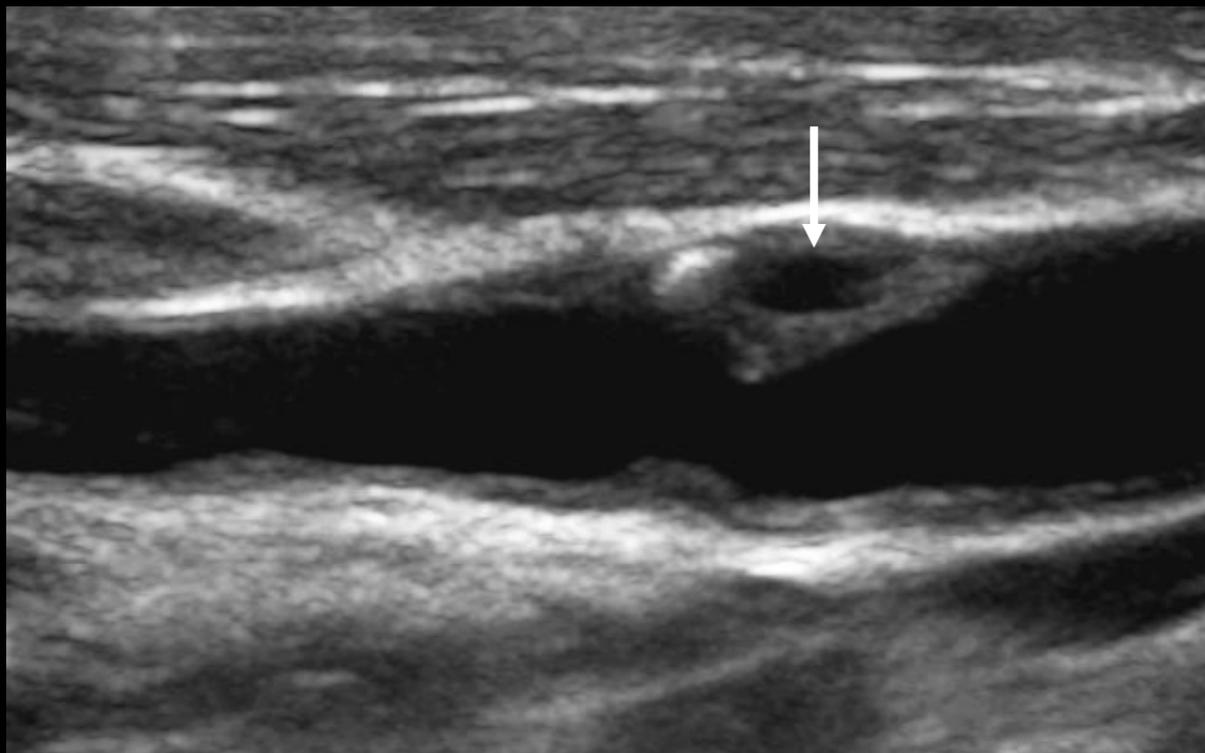

Mixed echo pattern with high and low levels of echogenicity

2D
75%
C 55
P Low
HGen

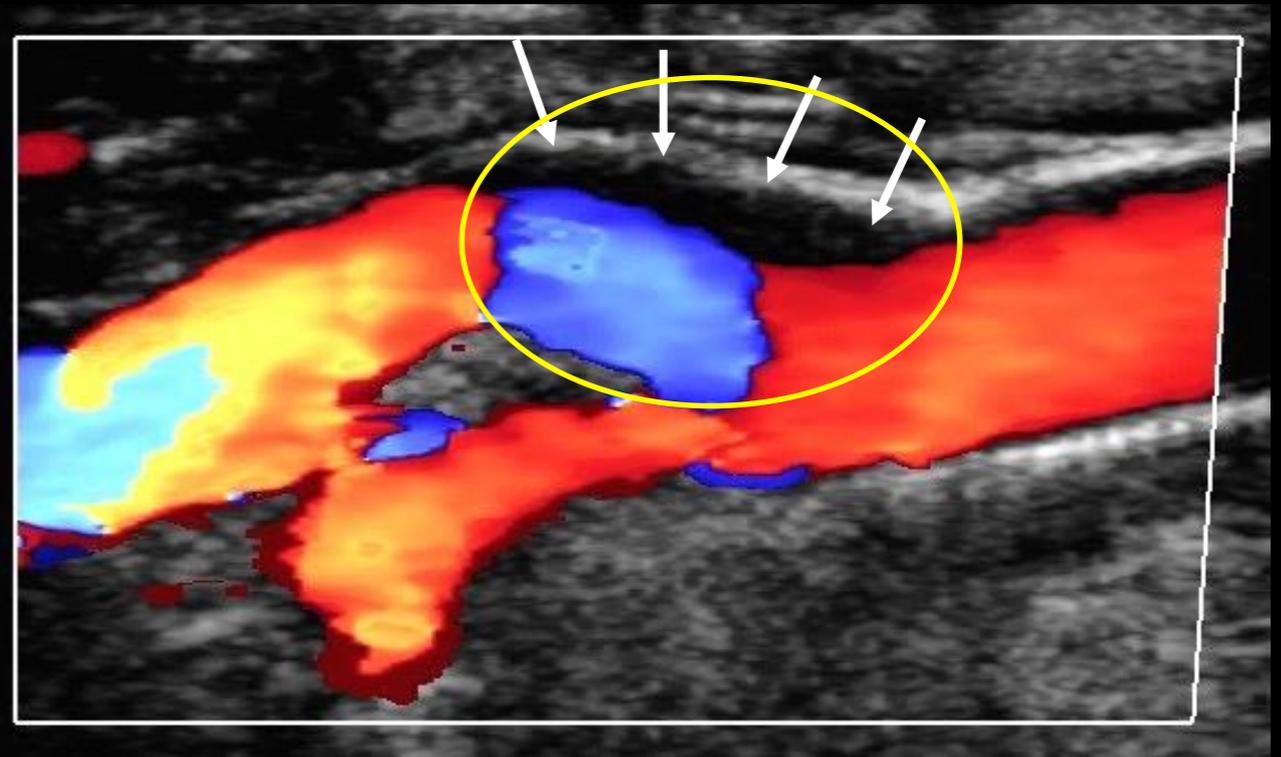

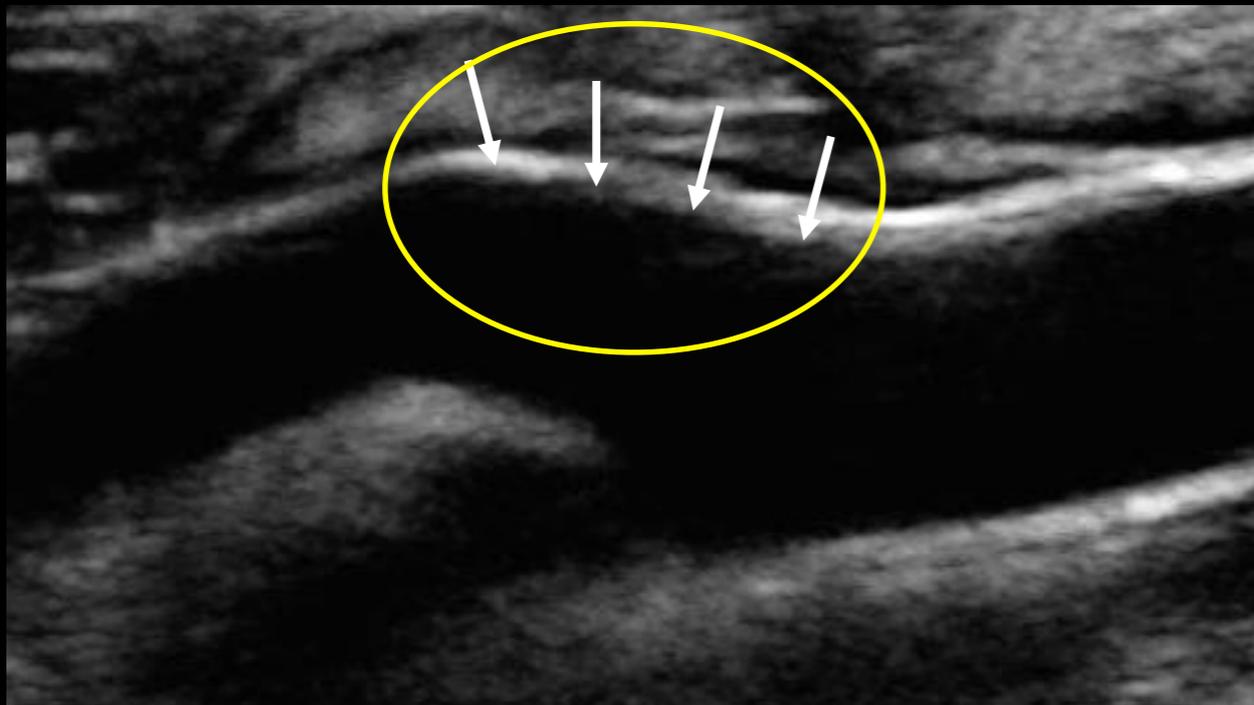

Heterogeneous Plaque

Focal anechoic area, which is the hallmark of intra-plaque hemorrhage

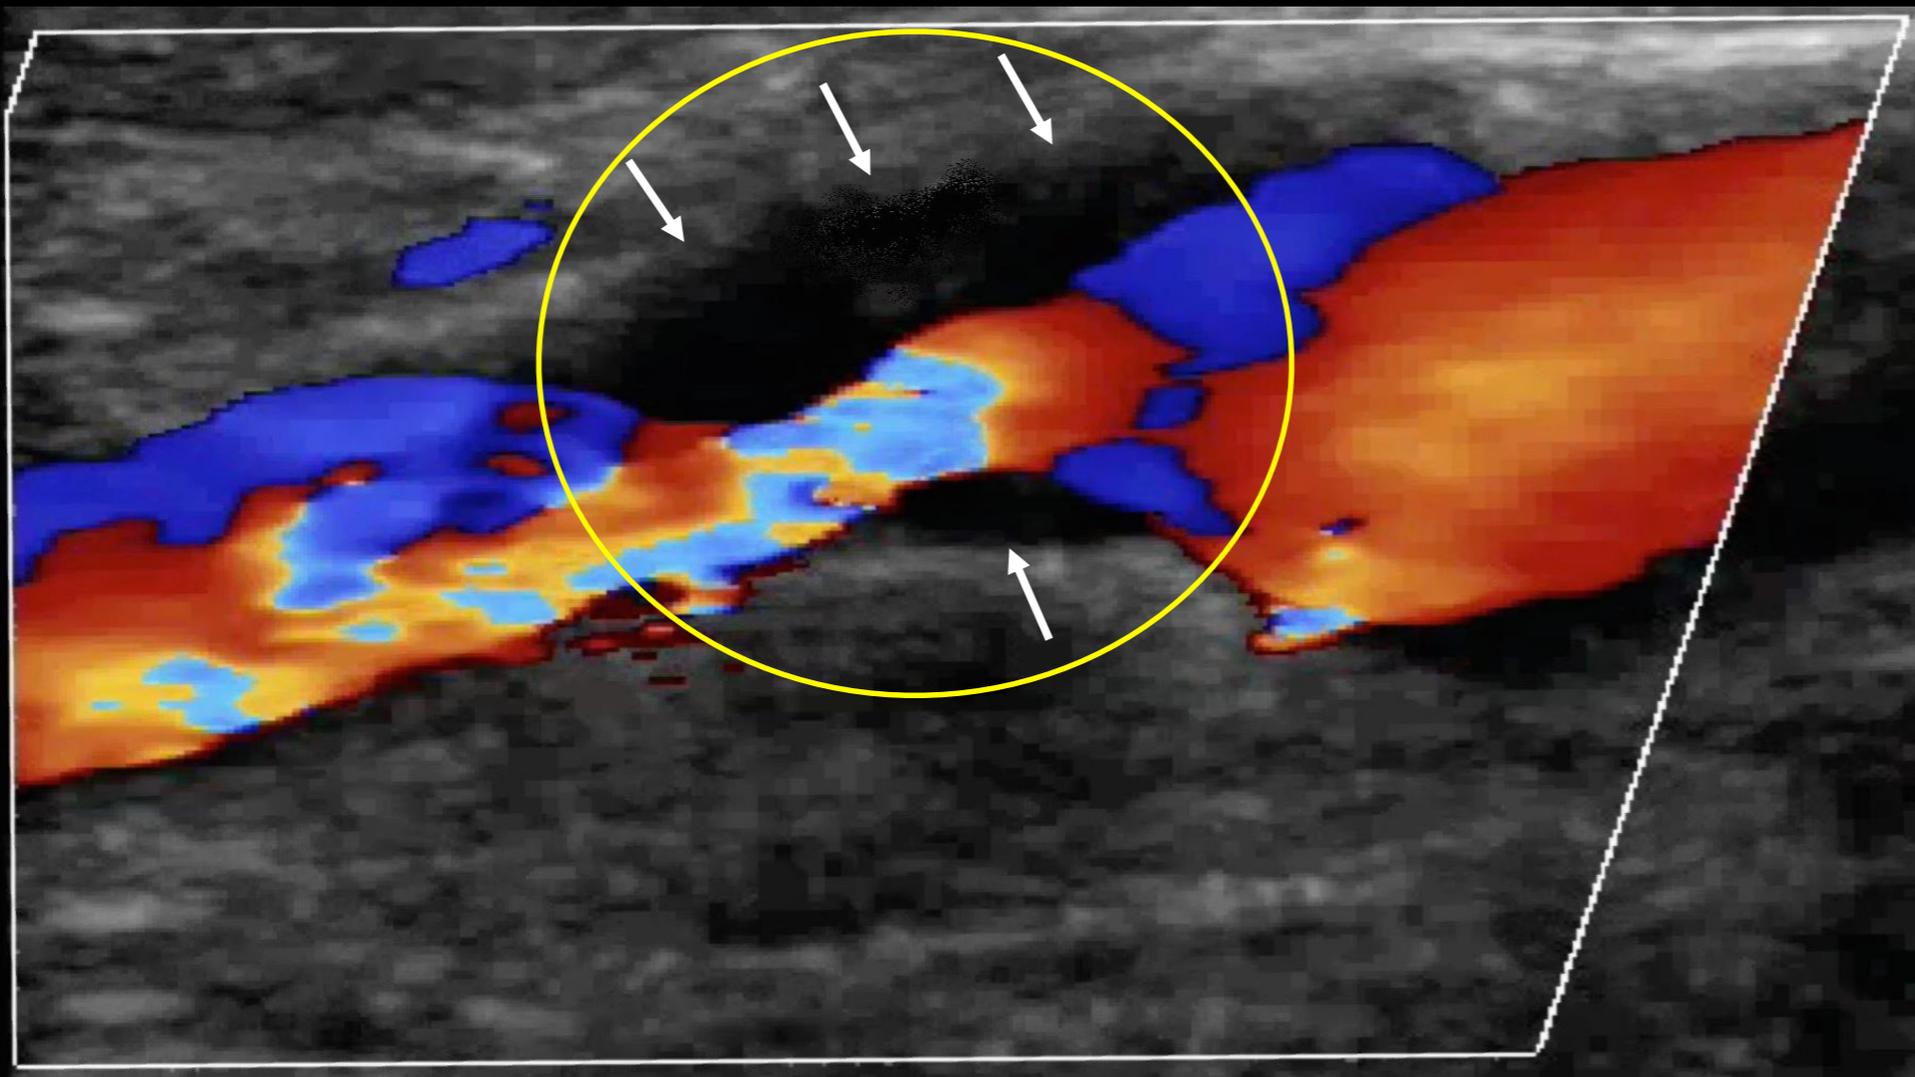

Echolucent Plaque

Independent risk factor for ischemic event;
whether or not stenosis is hemodynamically
significant

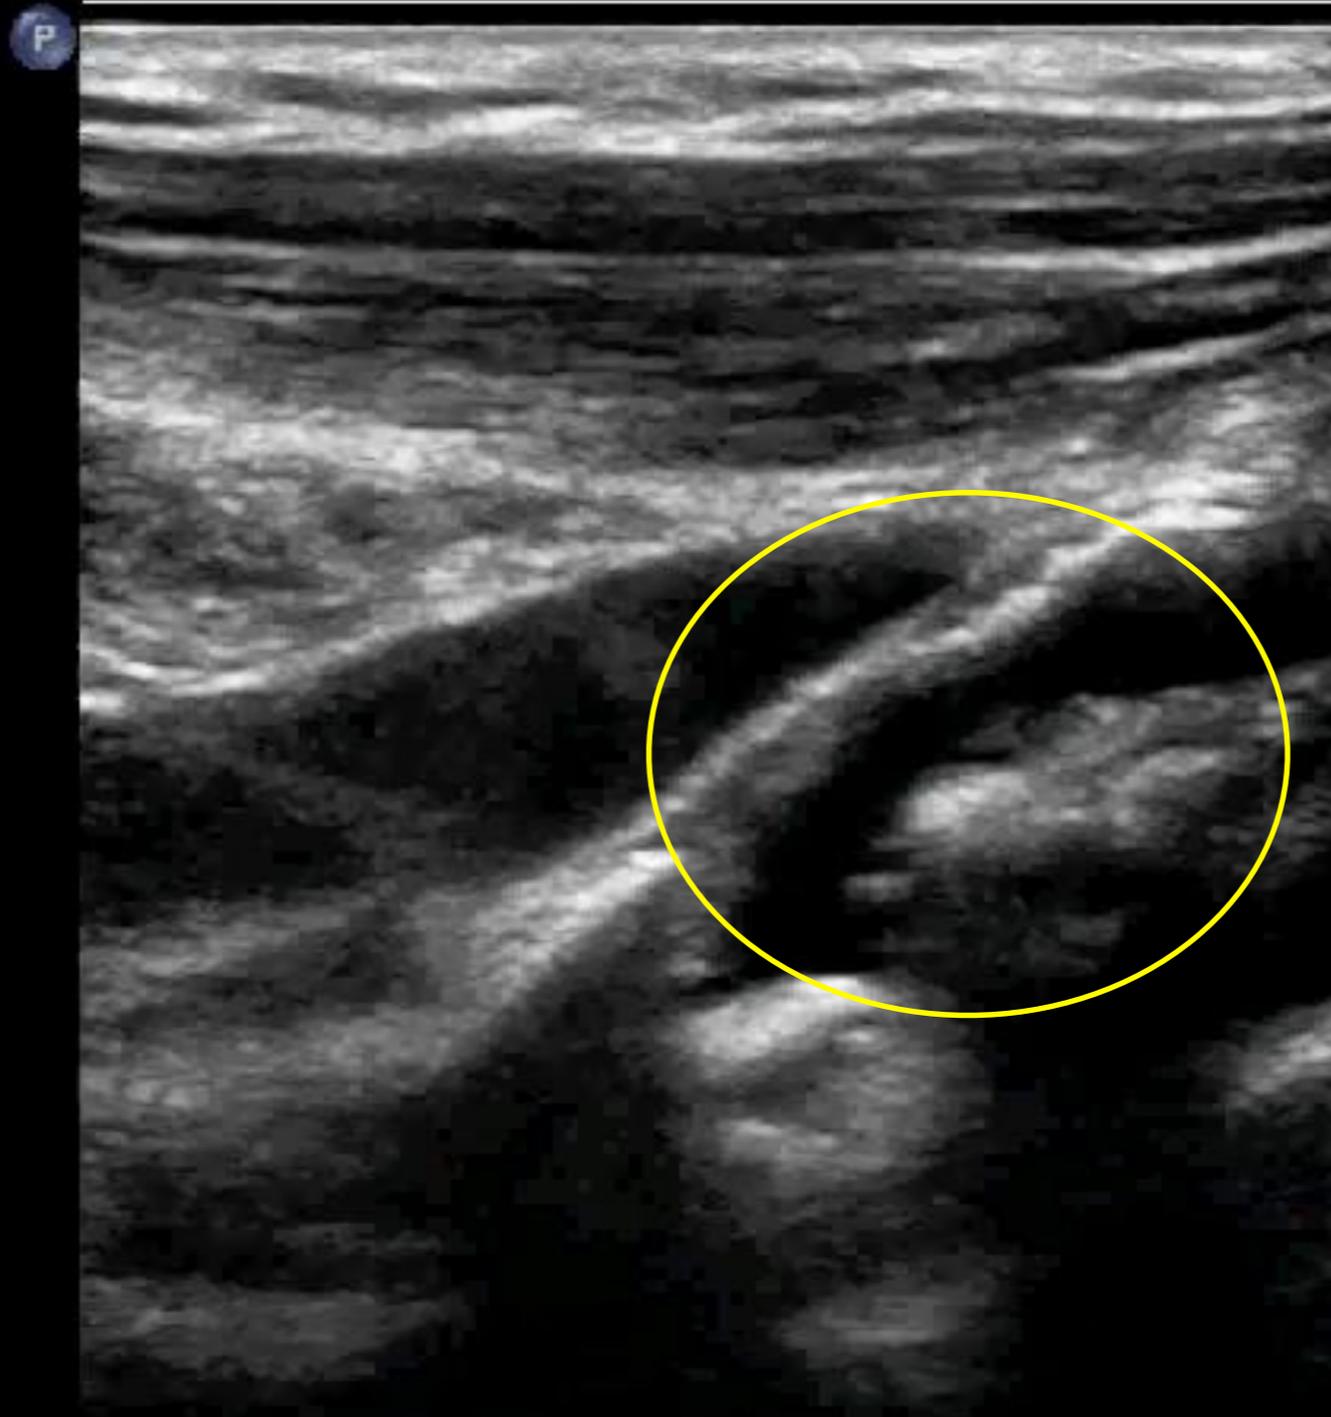

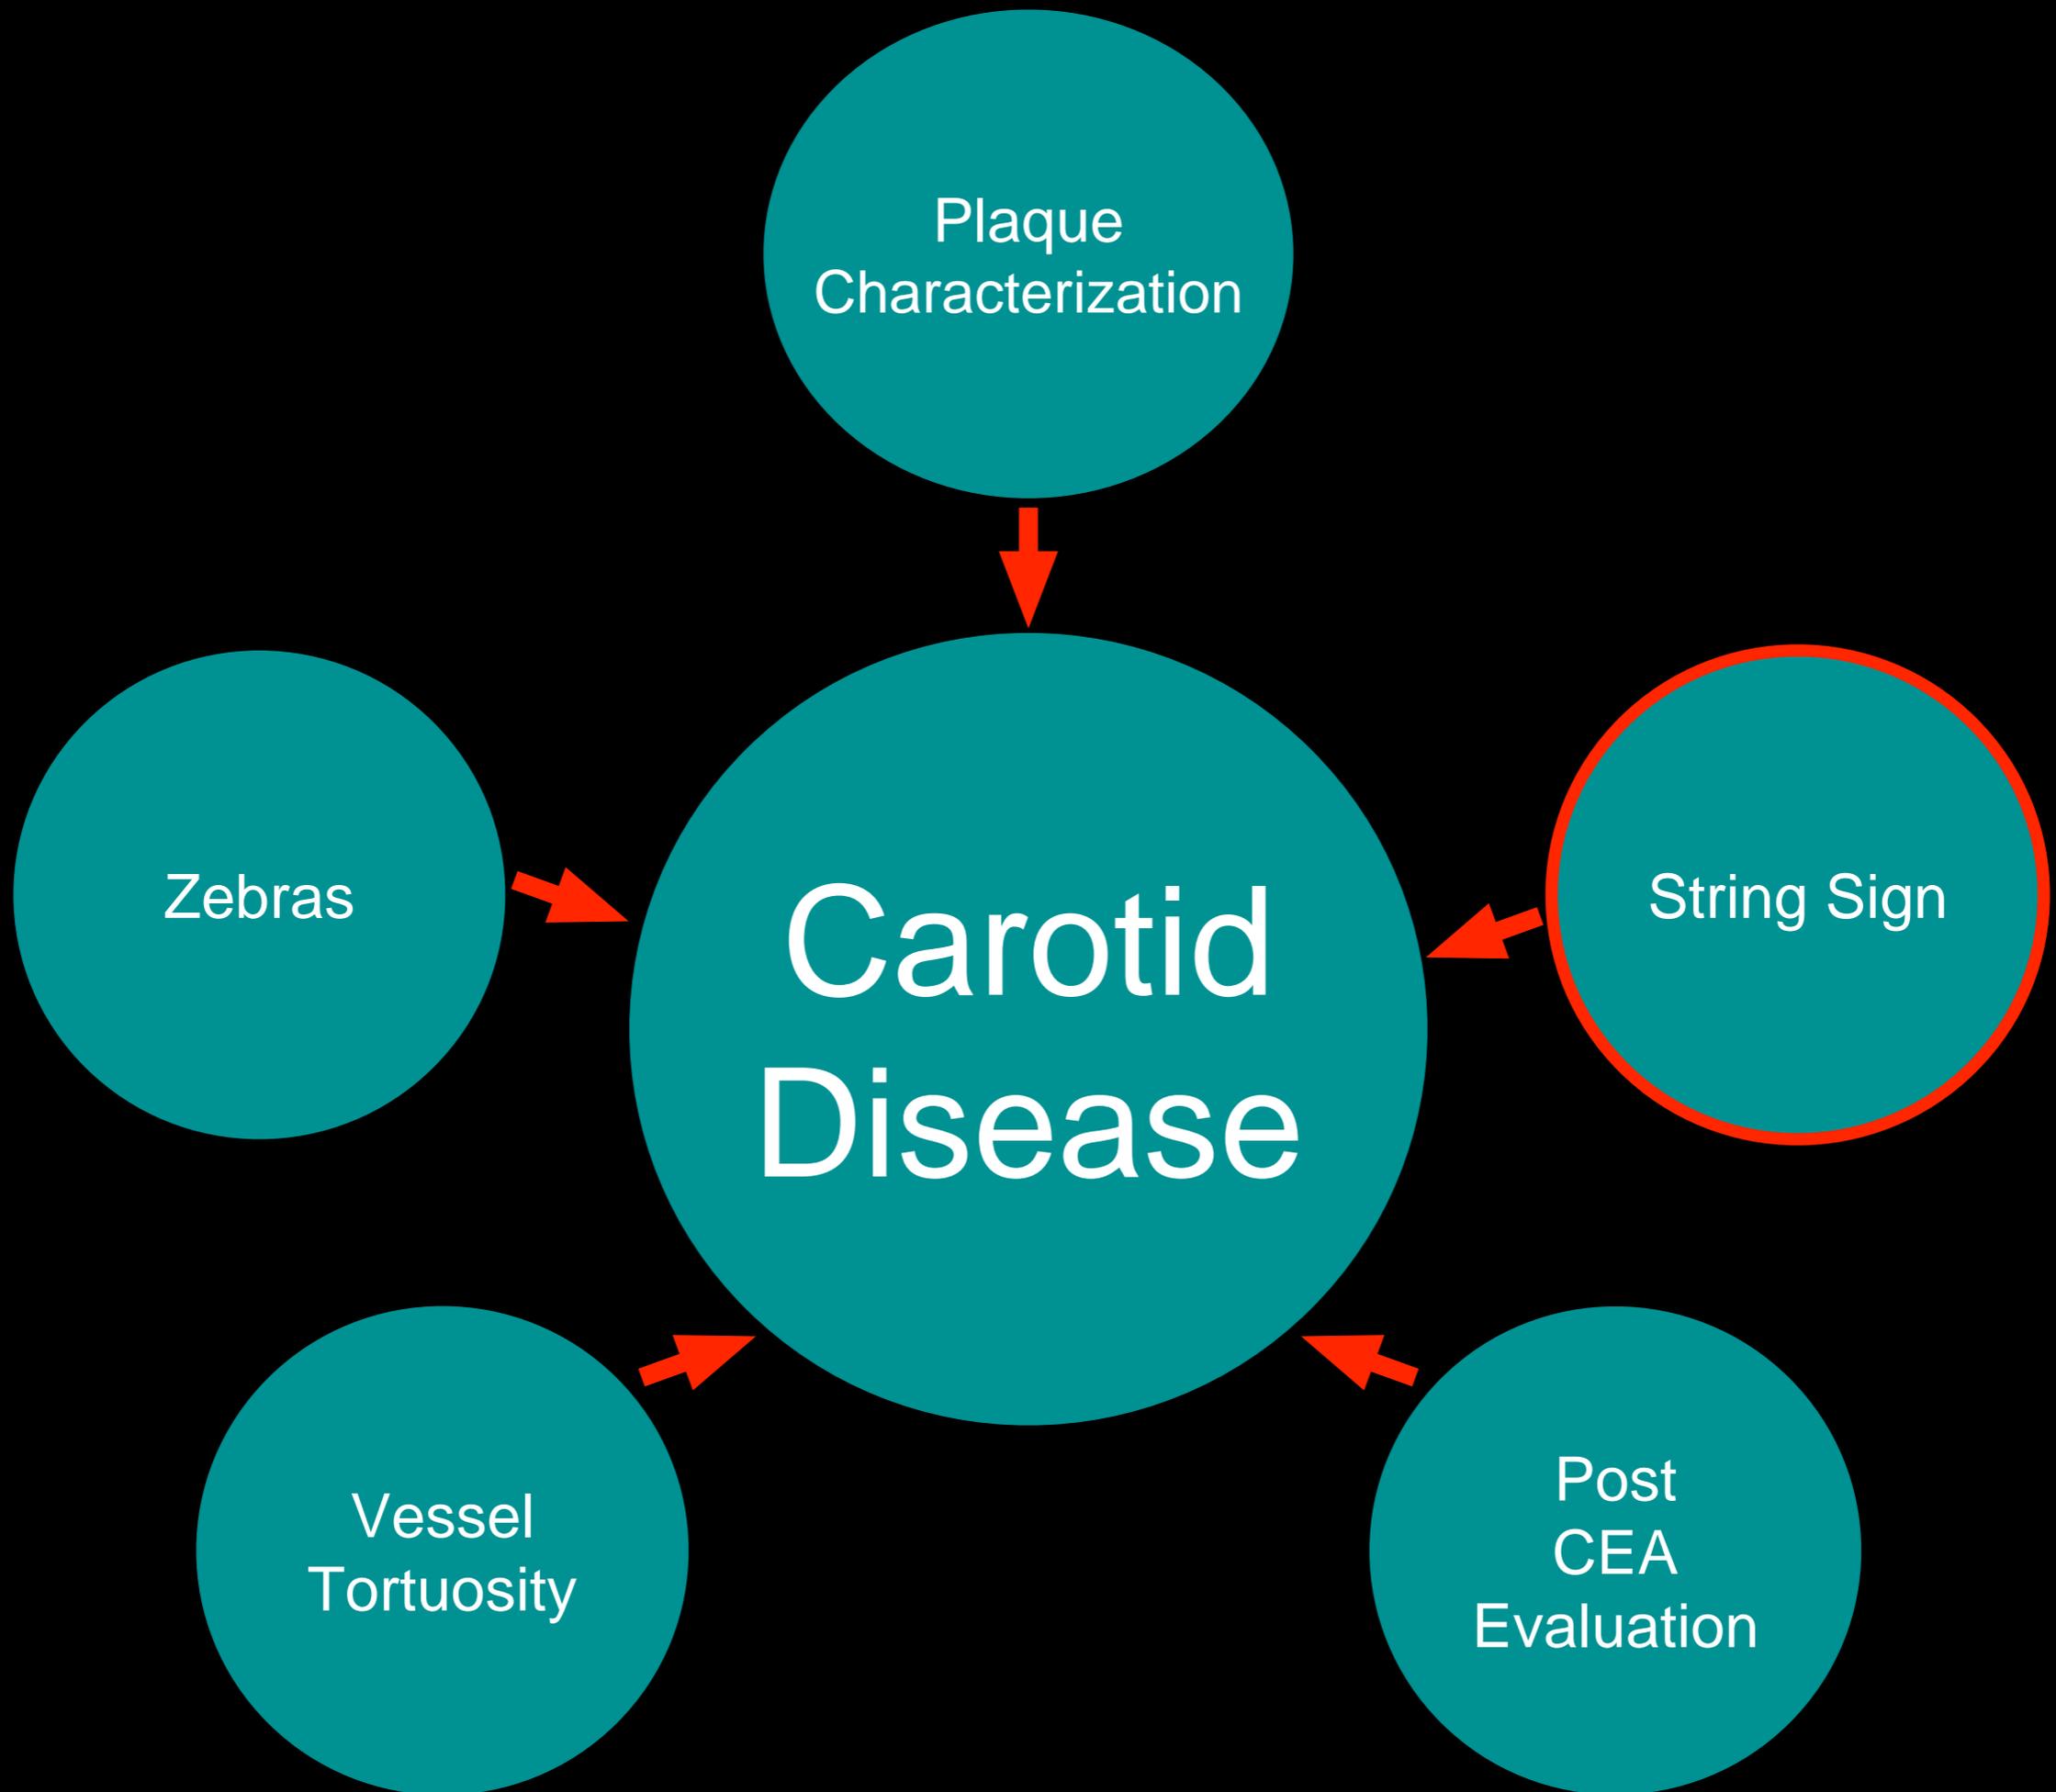

Echolucent Plaque

Echolucent lesions appear to be more likely to result in emboli post CAS vs. post CEA

Calcified Plaque with Mobile Atheroma

CEA
Evaluation

Vessel
Tortuosity

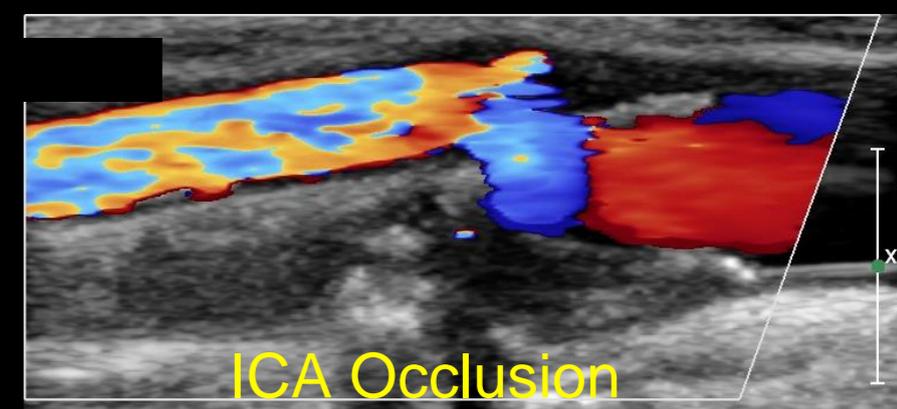

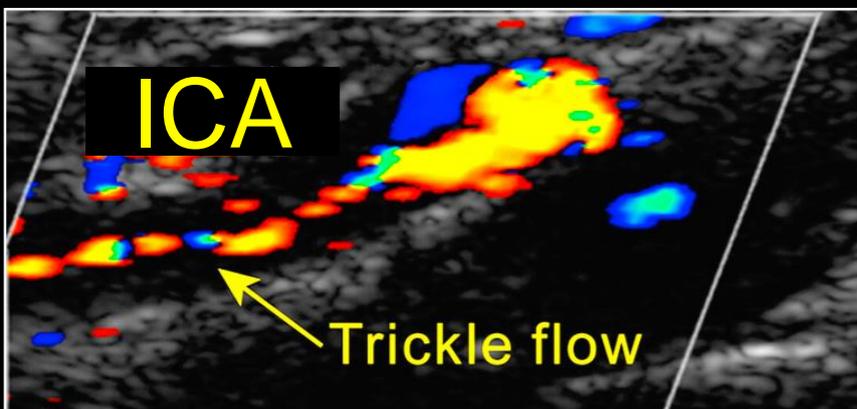

String Sign

- The ICA is typically long and tapers distally
- Post stenotic segment with markedly reduced vessel caliber size and low amplitude antegrade flow distally

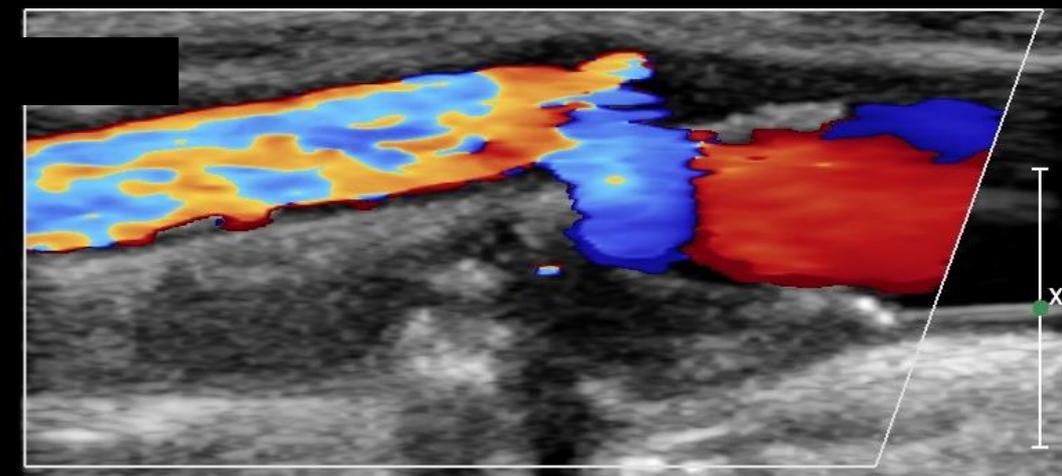

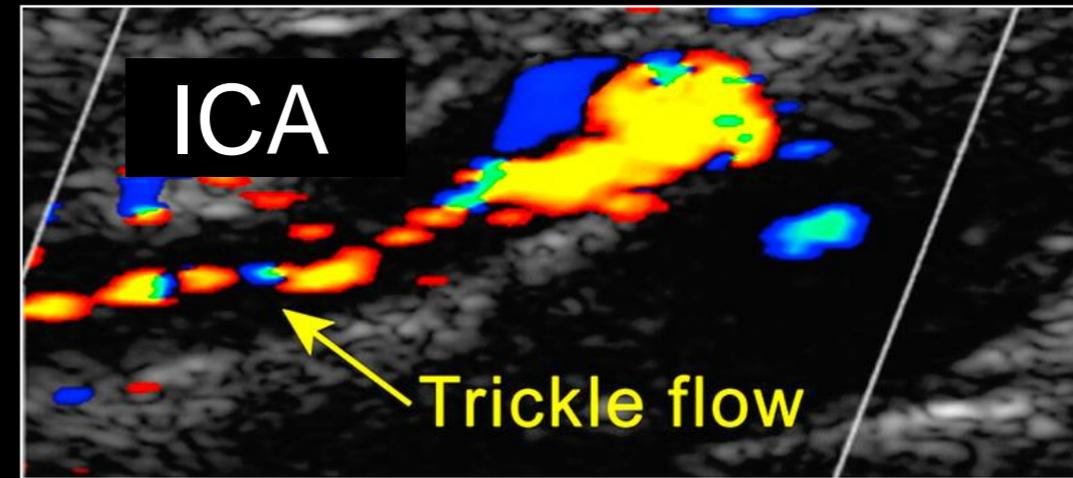

Optimizing Image Settings for Low Flow Detection

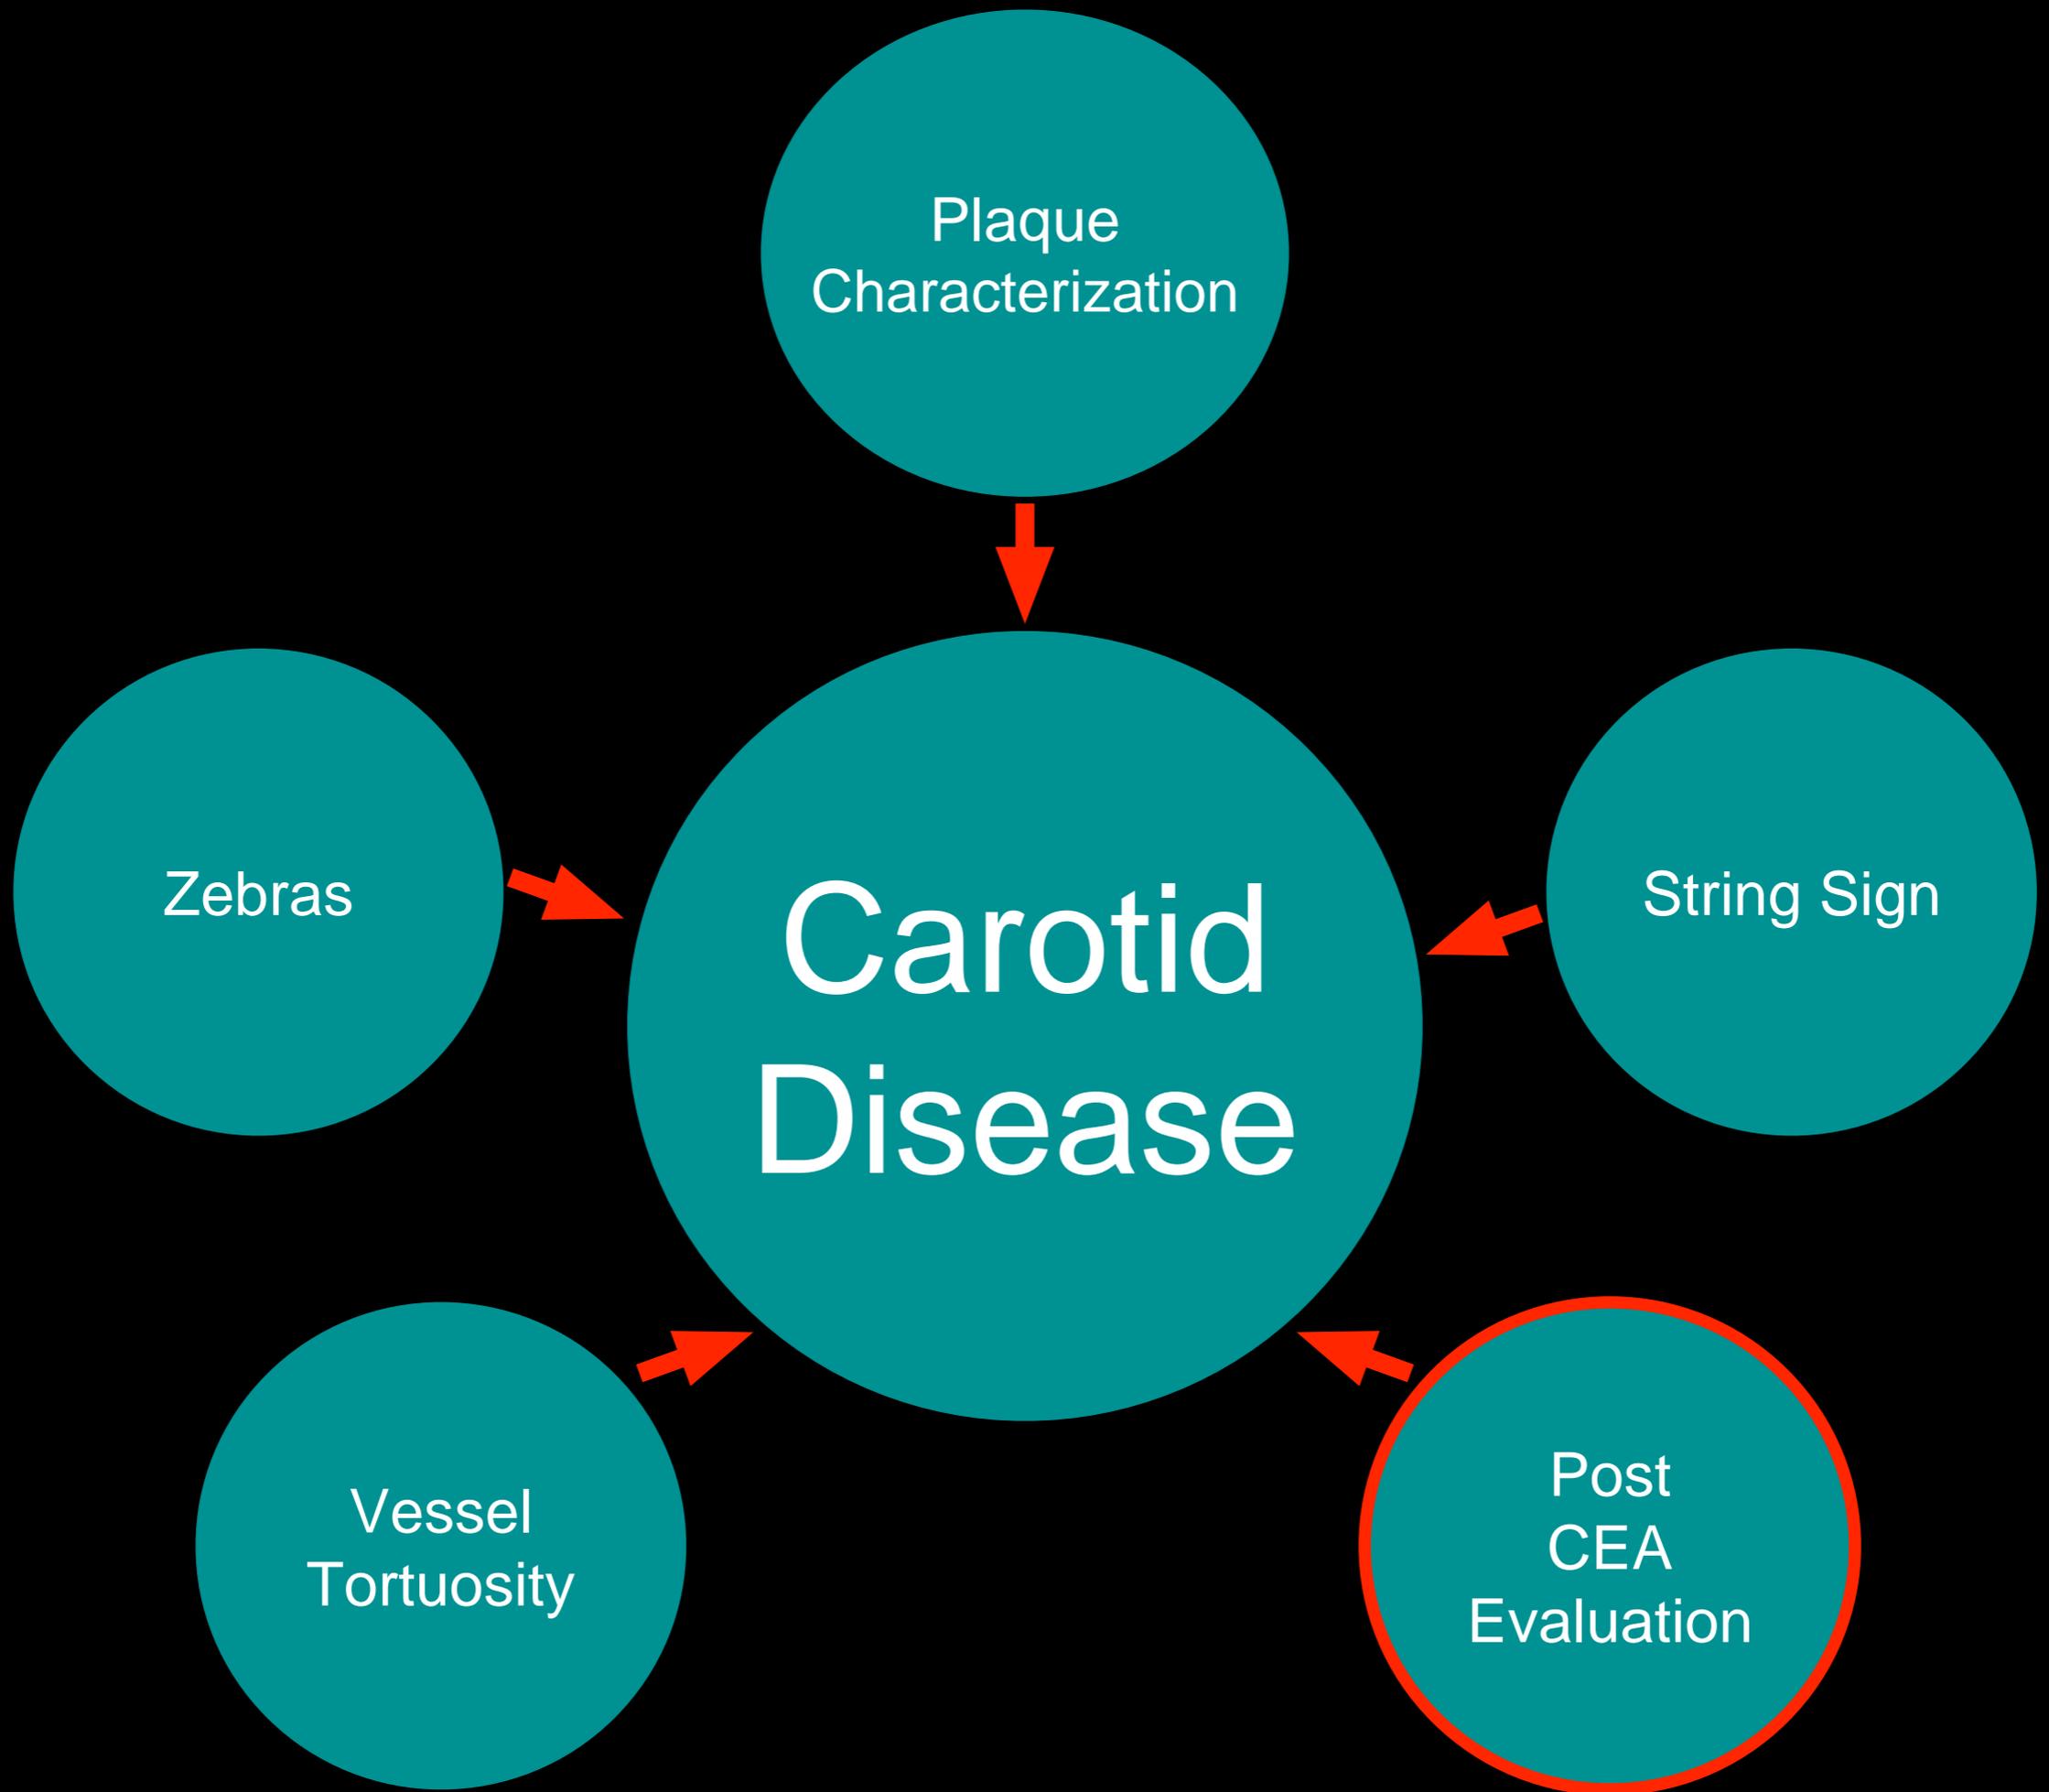

- **Color Flow**
- Decrease scale
- Increase gain
- Increase persistence
- Low wall filter
- Steer & adjust box size
- Spectral Doppler
- Decrease scale
- Increase gain
- Low wall filter
- Utilize 60°

String Sign

- It's important to distinguish between ICA near occlusion vs. total occlusion
- Diagnosing an ICA as occluded when patent, but significantly stenotic could result in stroke or total occlusion

Carotid
Disease

String Sign

Vessel
Tortuosity

Post
CEA
Evaluation

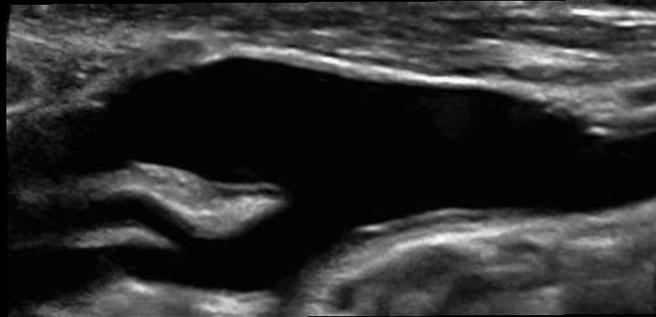

Post CEA Evaluation

- Annual incidence of restenosis or occlusion
~1%-4.5%
- Early recurrent stenosis usually develops within 2 years of CEA and represents scar/neointimal hyperplasia
- After 3 years, new post CEA lesions must be evaluated for the possibility of neo-atherosclerosis
- Both diseases have a distinctly different natural history, with interventional outcomes
- Neo-atherosclerosis has a less benign course

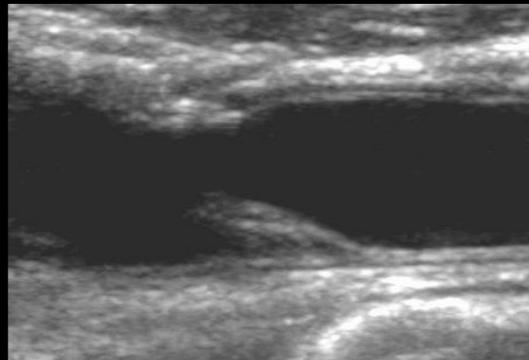

Post CEA Evaluation

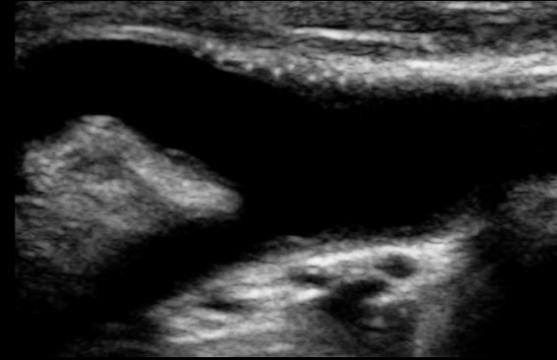

Intra-op injury, i.e., arterial clamping, intraluminal shunt insertion or suture placement may cause intimal hyperplasia

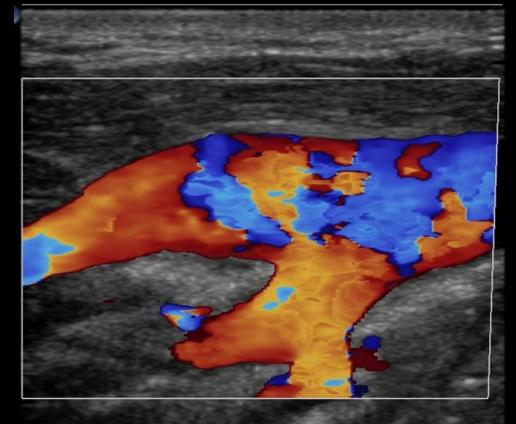

Proximal And Distal Endpoint

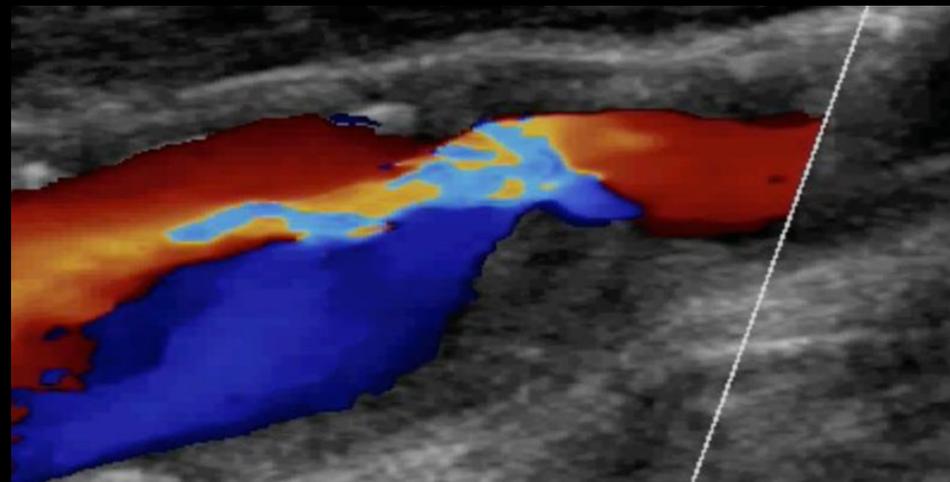

Flap Or Shelf

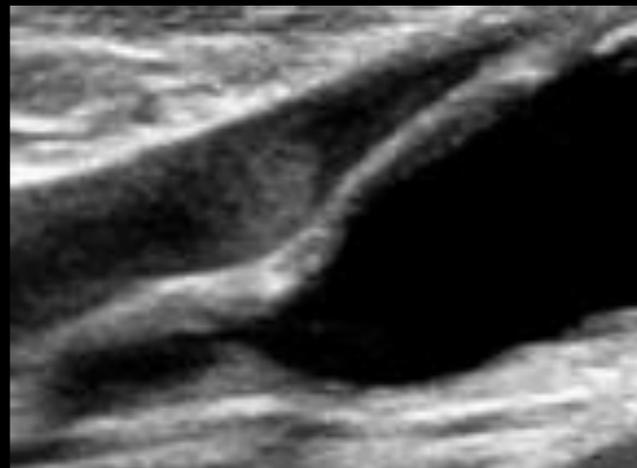

Post CEA at 1 Month

Patent Patch

Intimal Hyperplastic Lesion at 1 year

Distal End Point

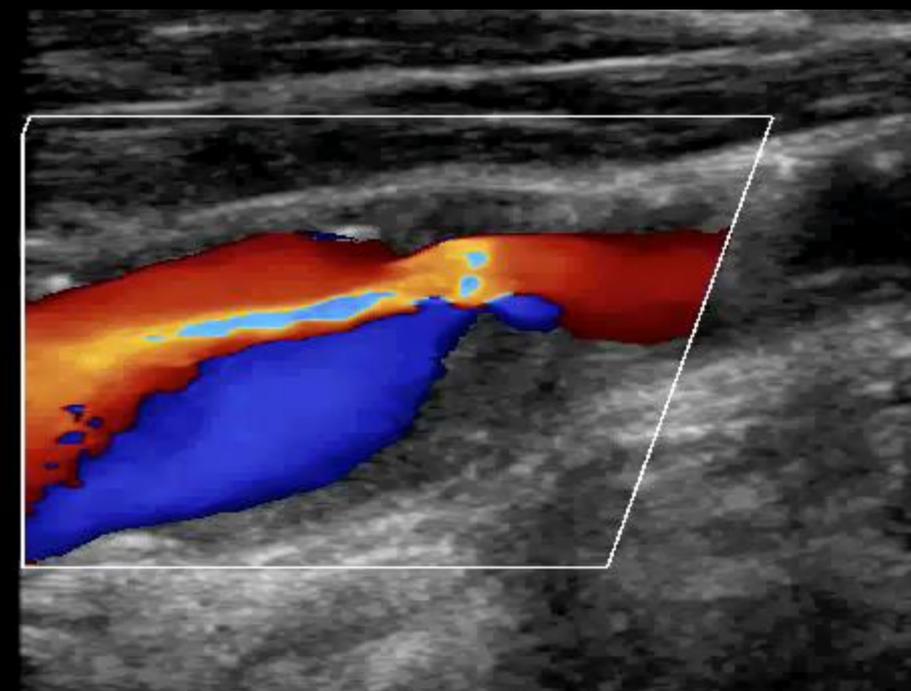

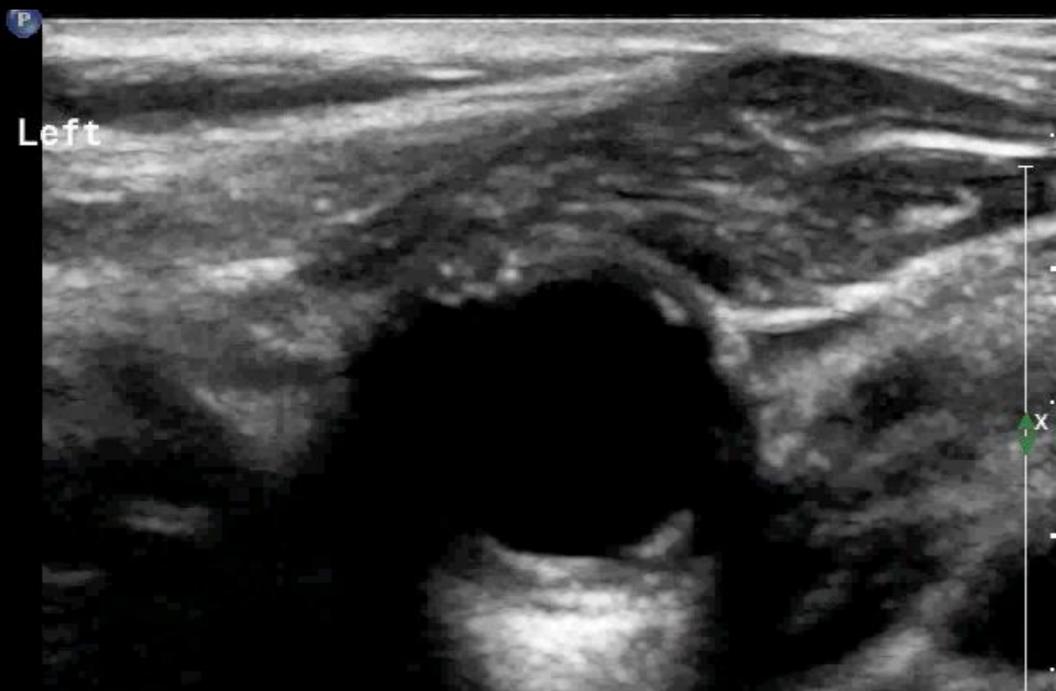

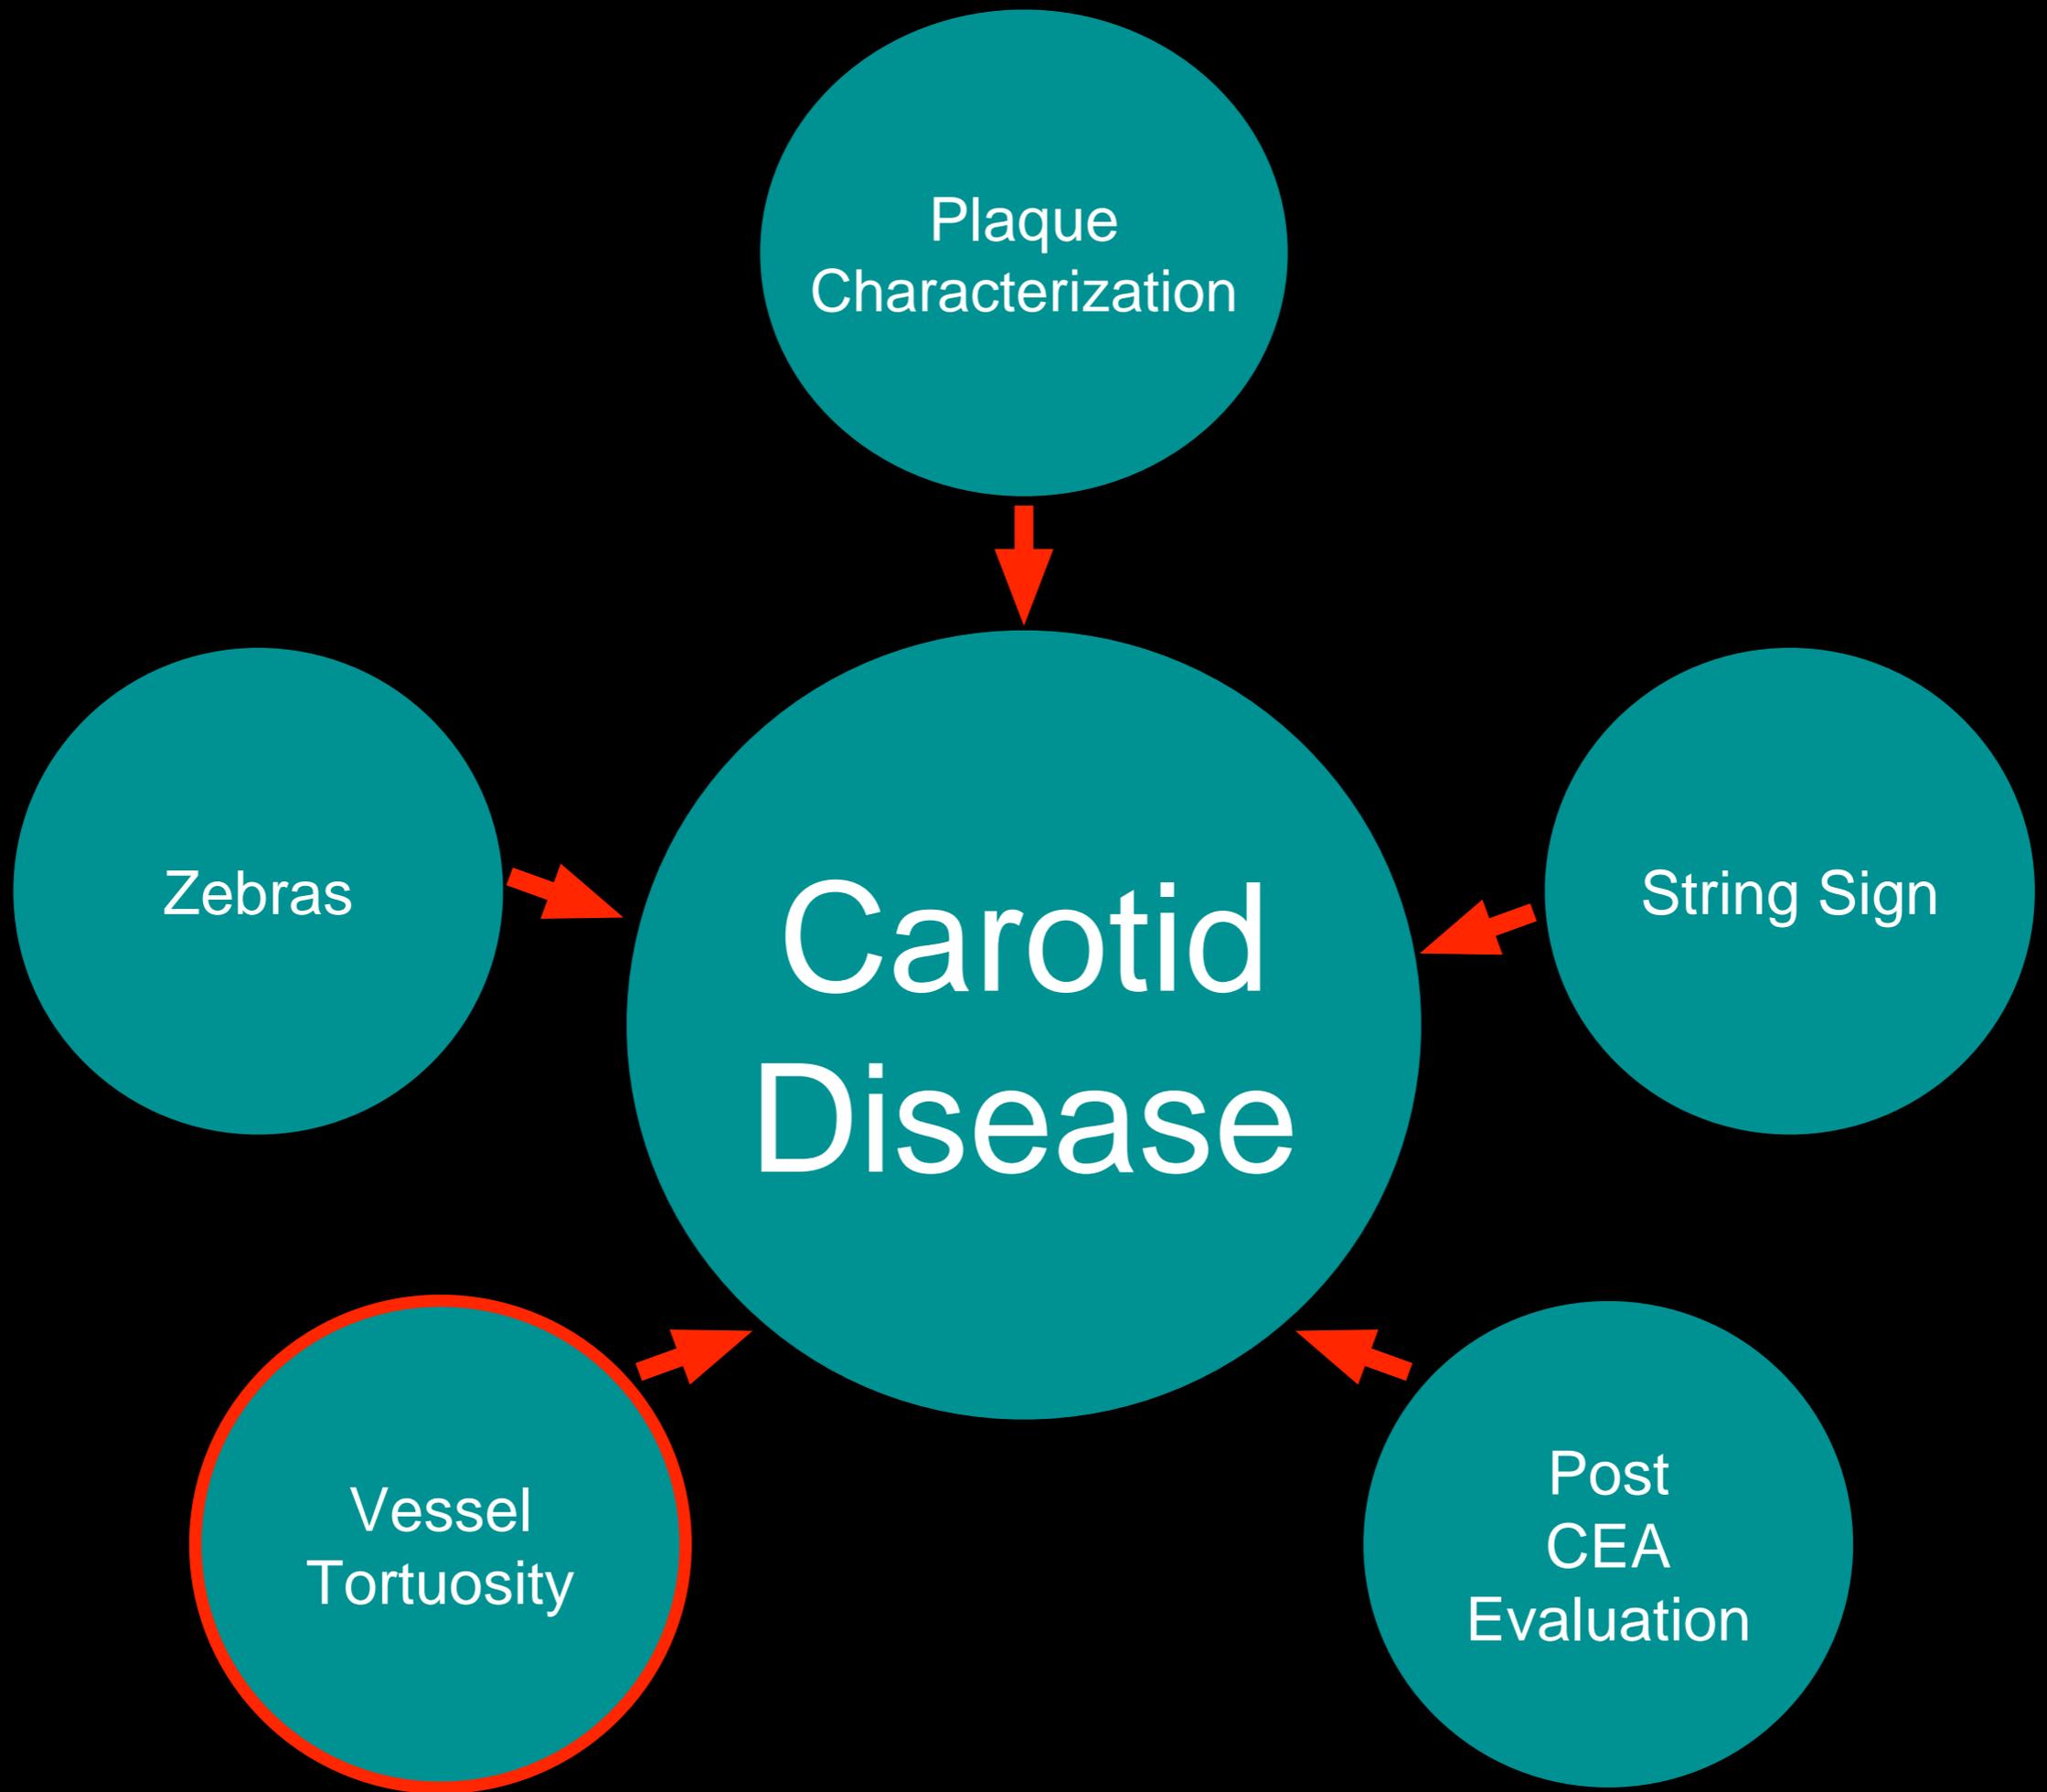

S/P CEA 10 Years

Post CEA Evaluation

CDU of CEA Restenosis

- Common 1-35%; < 8% symptomatic
- Type of closure: primary vs. patch angioplasty (decreased rates)
- Debatable whether clinically significant to continue CDU surveillance due to low recurrent rate of restenosis

Plaque

Zebras

Carotid
Disease

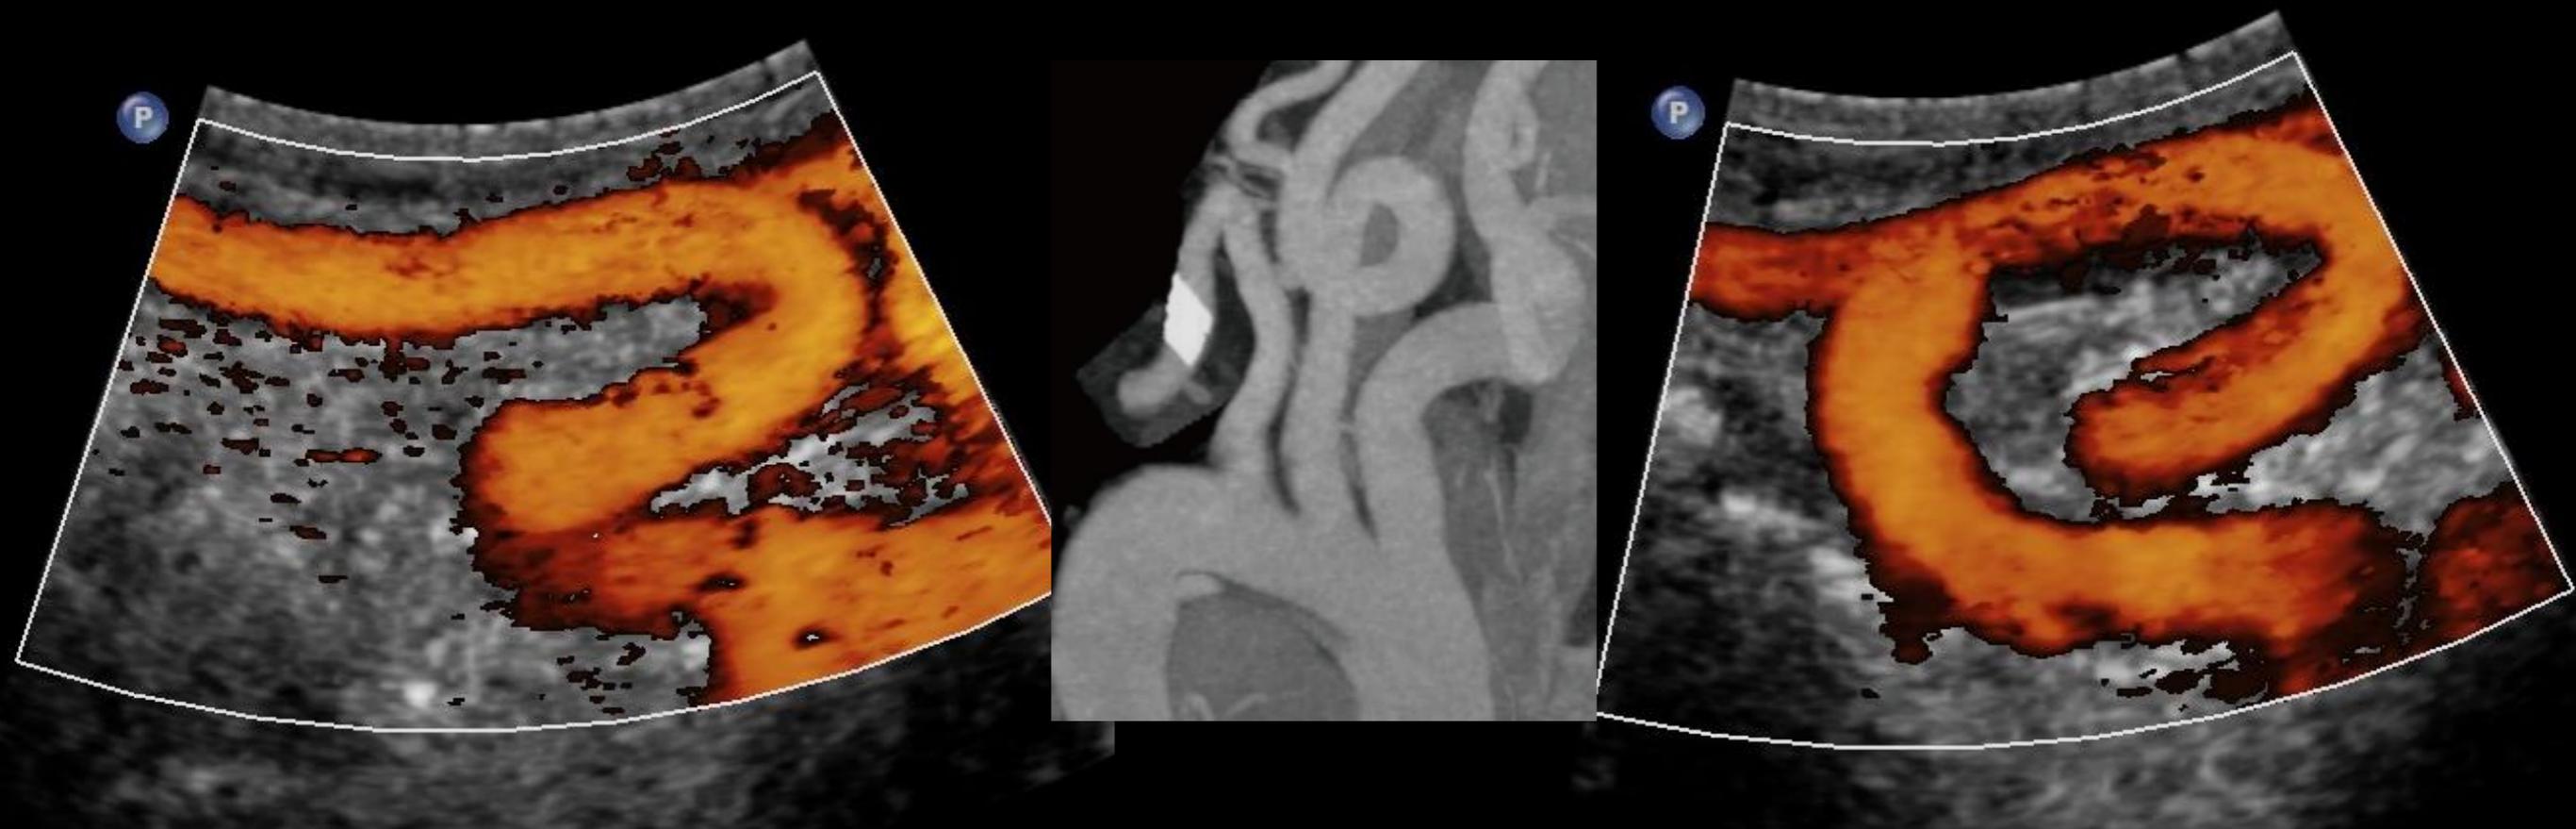

String Sign

Vessel
Tortuosity

Post
CEA
Evaluation

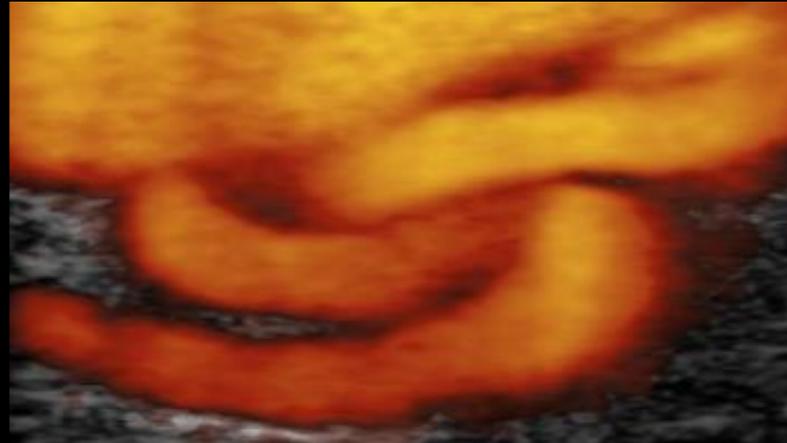

Proximal CCA Tortuosity

Tortuosity of the CCA increases the difficulty of axis in CAS, increases the risk of complication with vessel injury, and loss of guide support, etc.

ICA Tortuosity

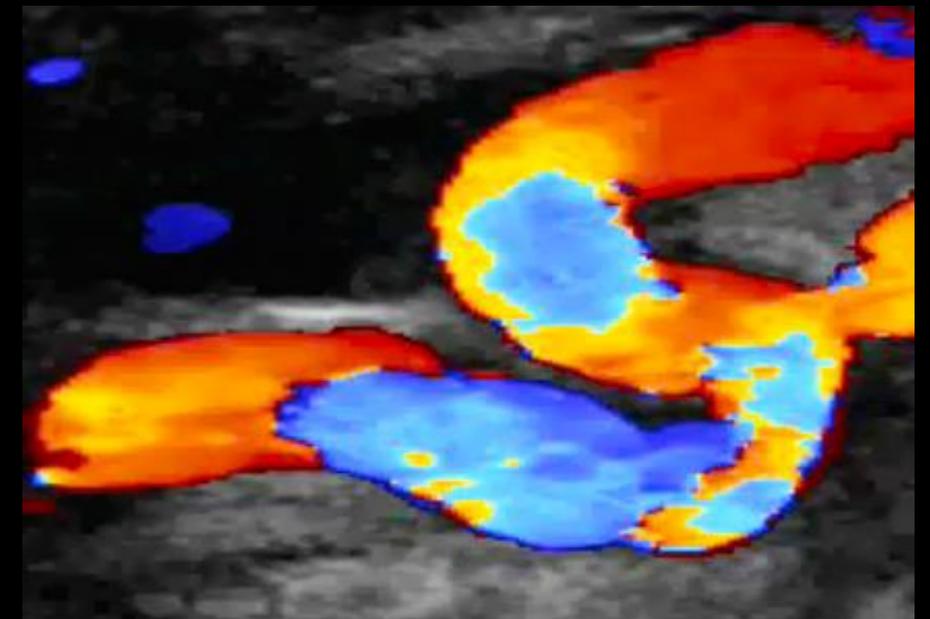

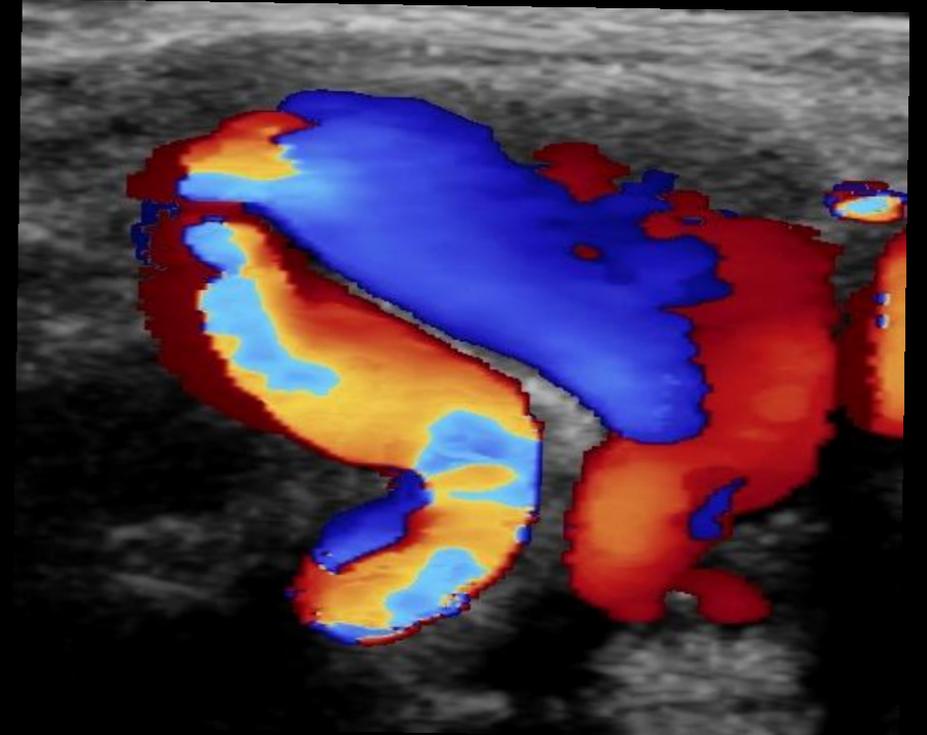

Distal ICA tortuosity may present challenges that complicate placement of a distal embolic protection device and stent

ICA Tortuosity

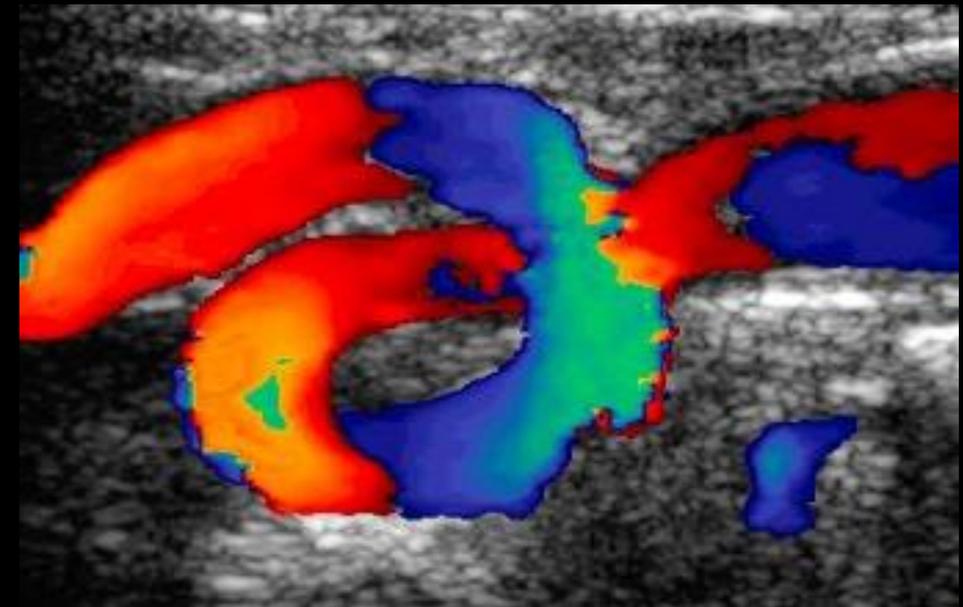

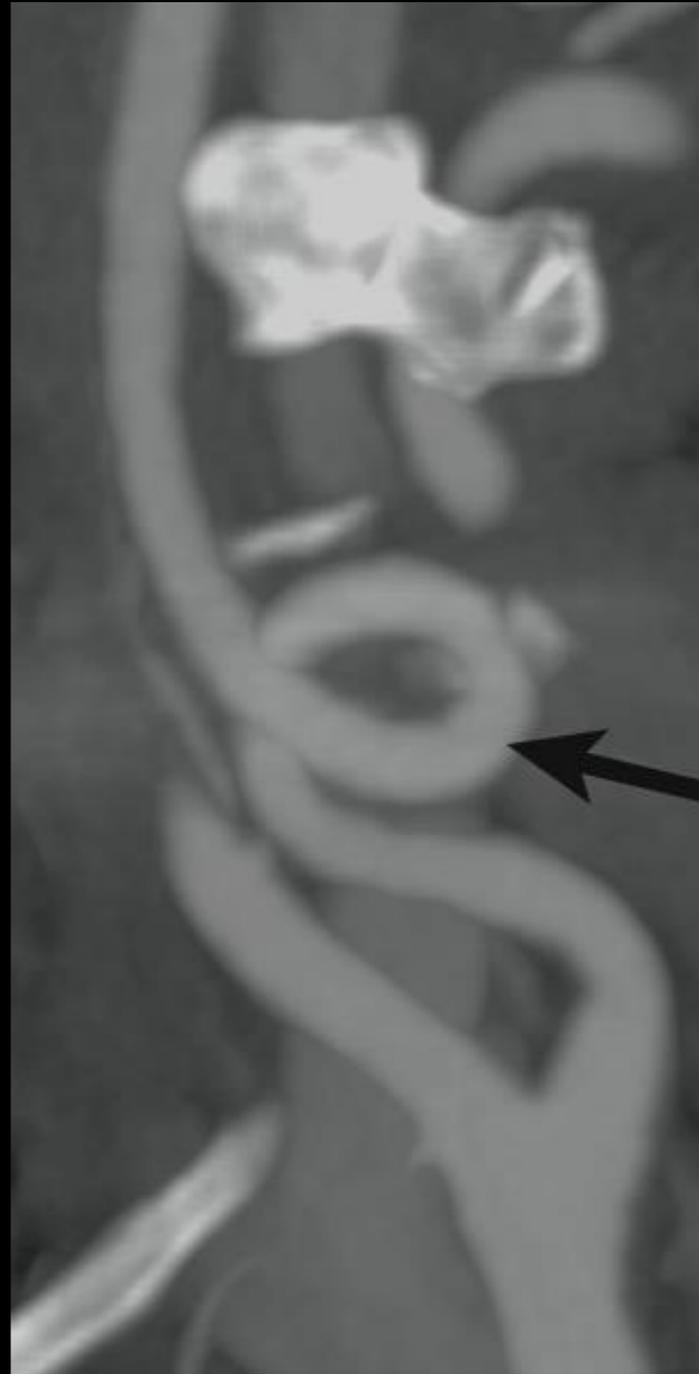

Kinking 5%

~27% of which
is bilateral

ICA Tortuosity

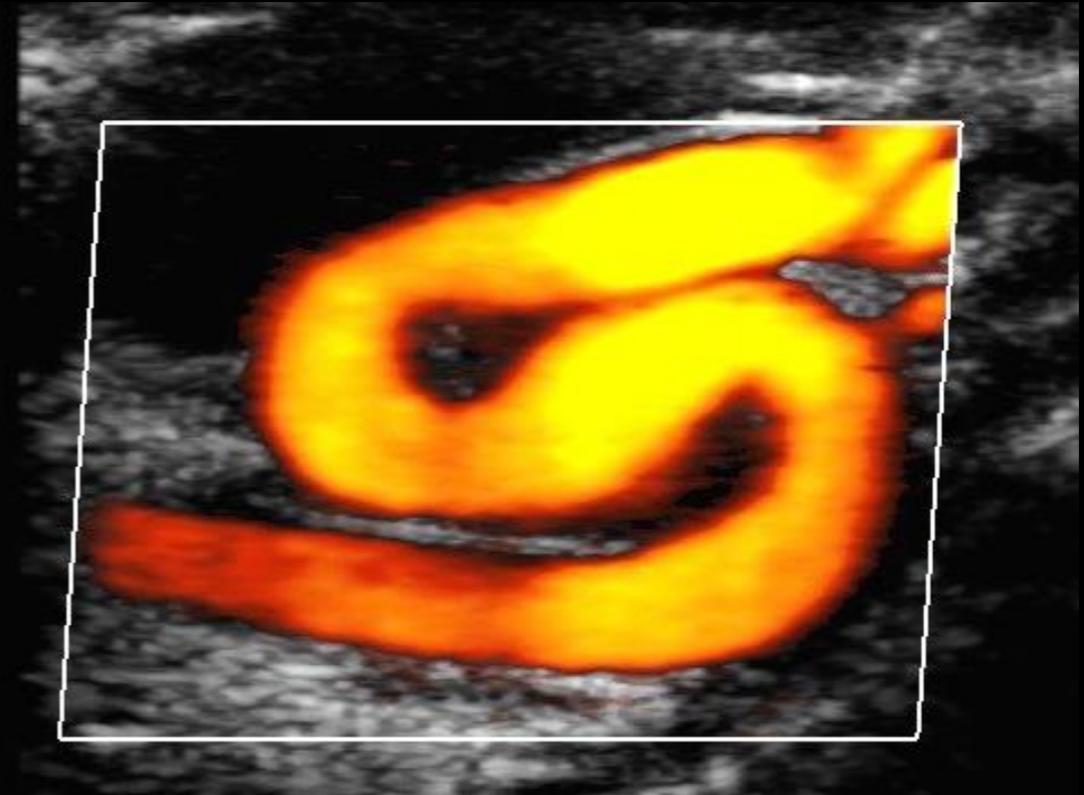

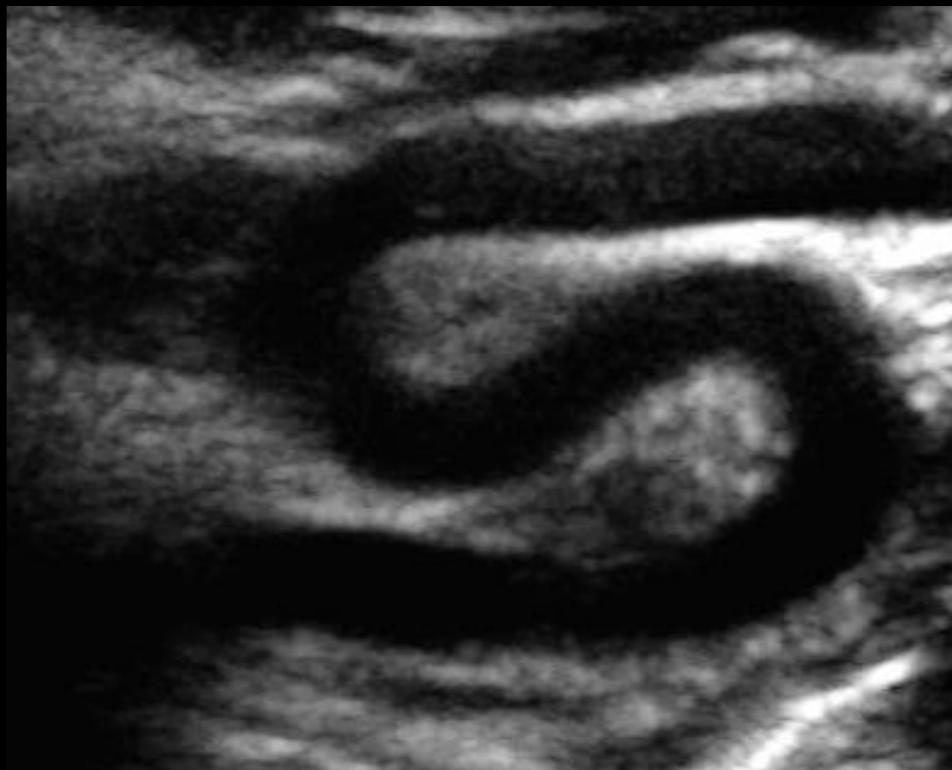

Coiling 6%
~53% of which
is bilateral

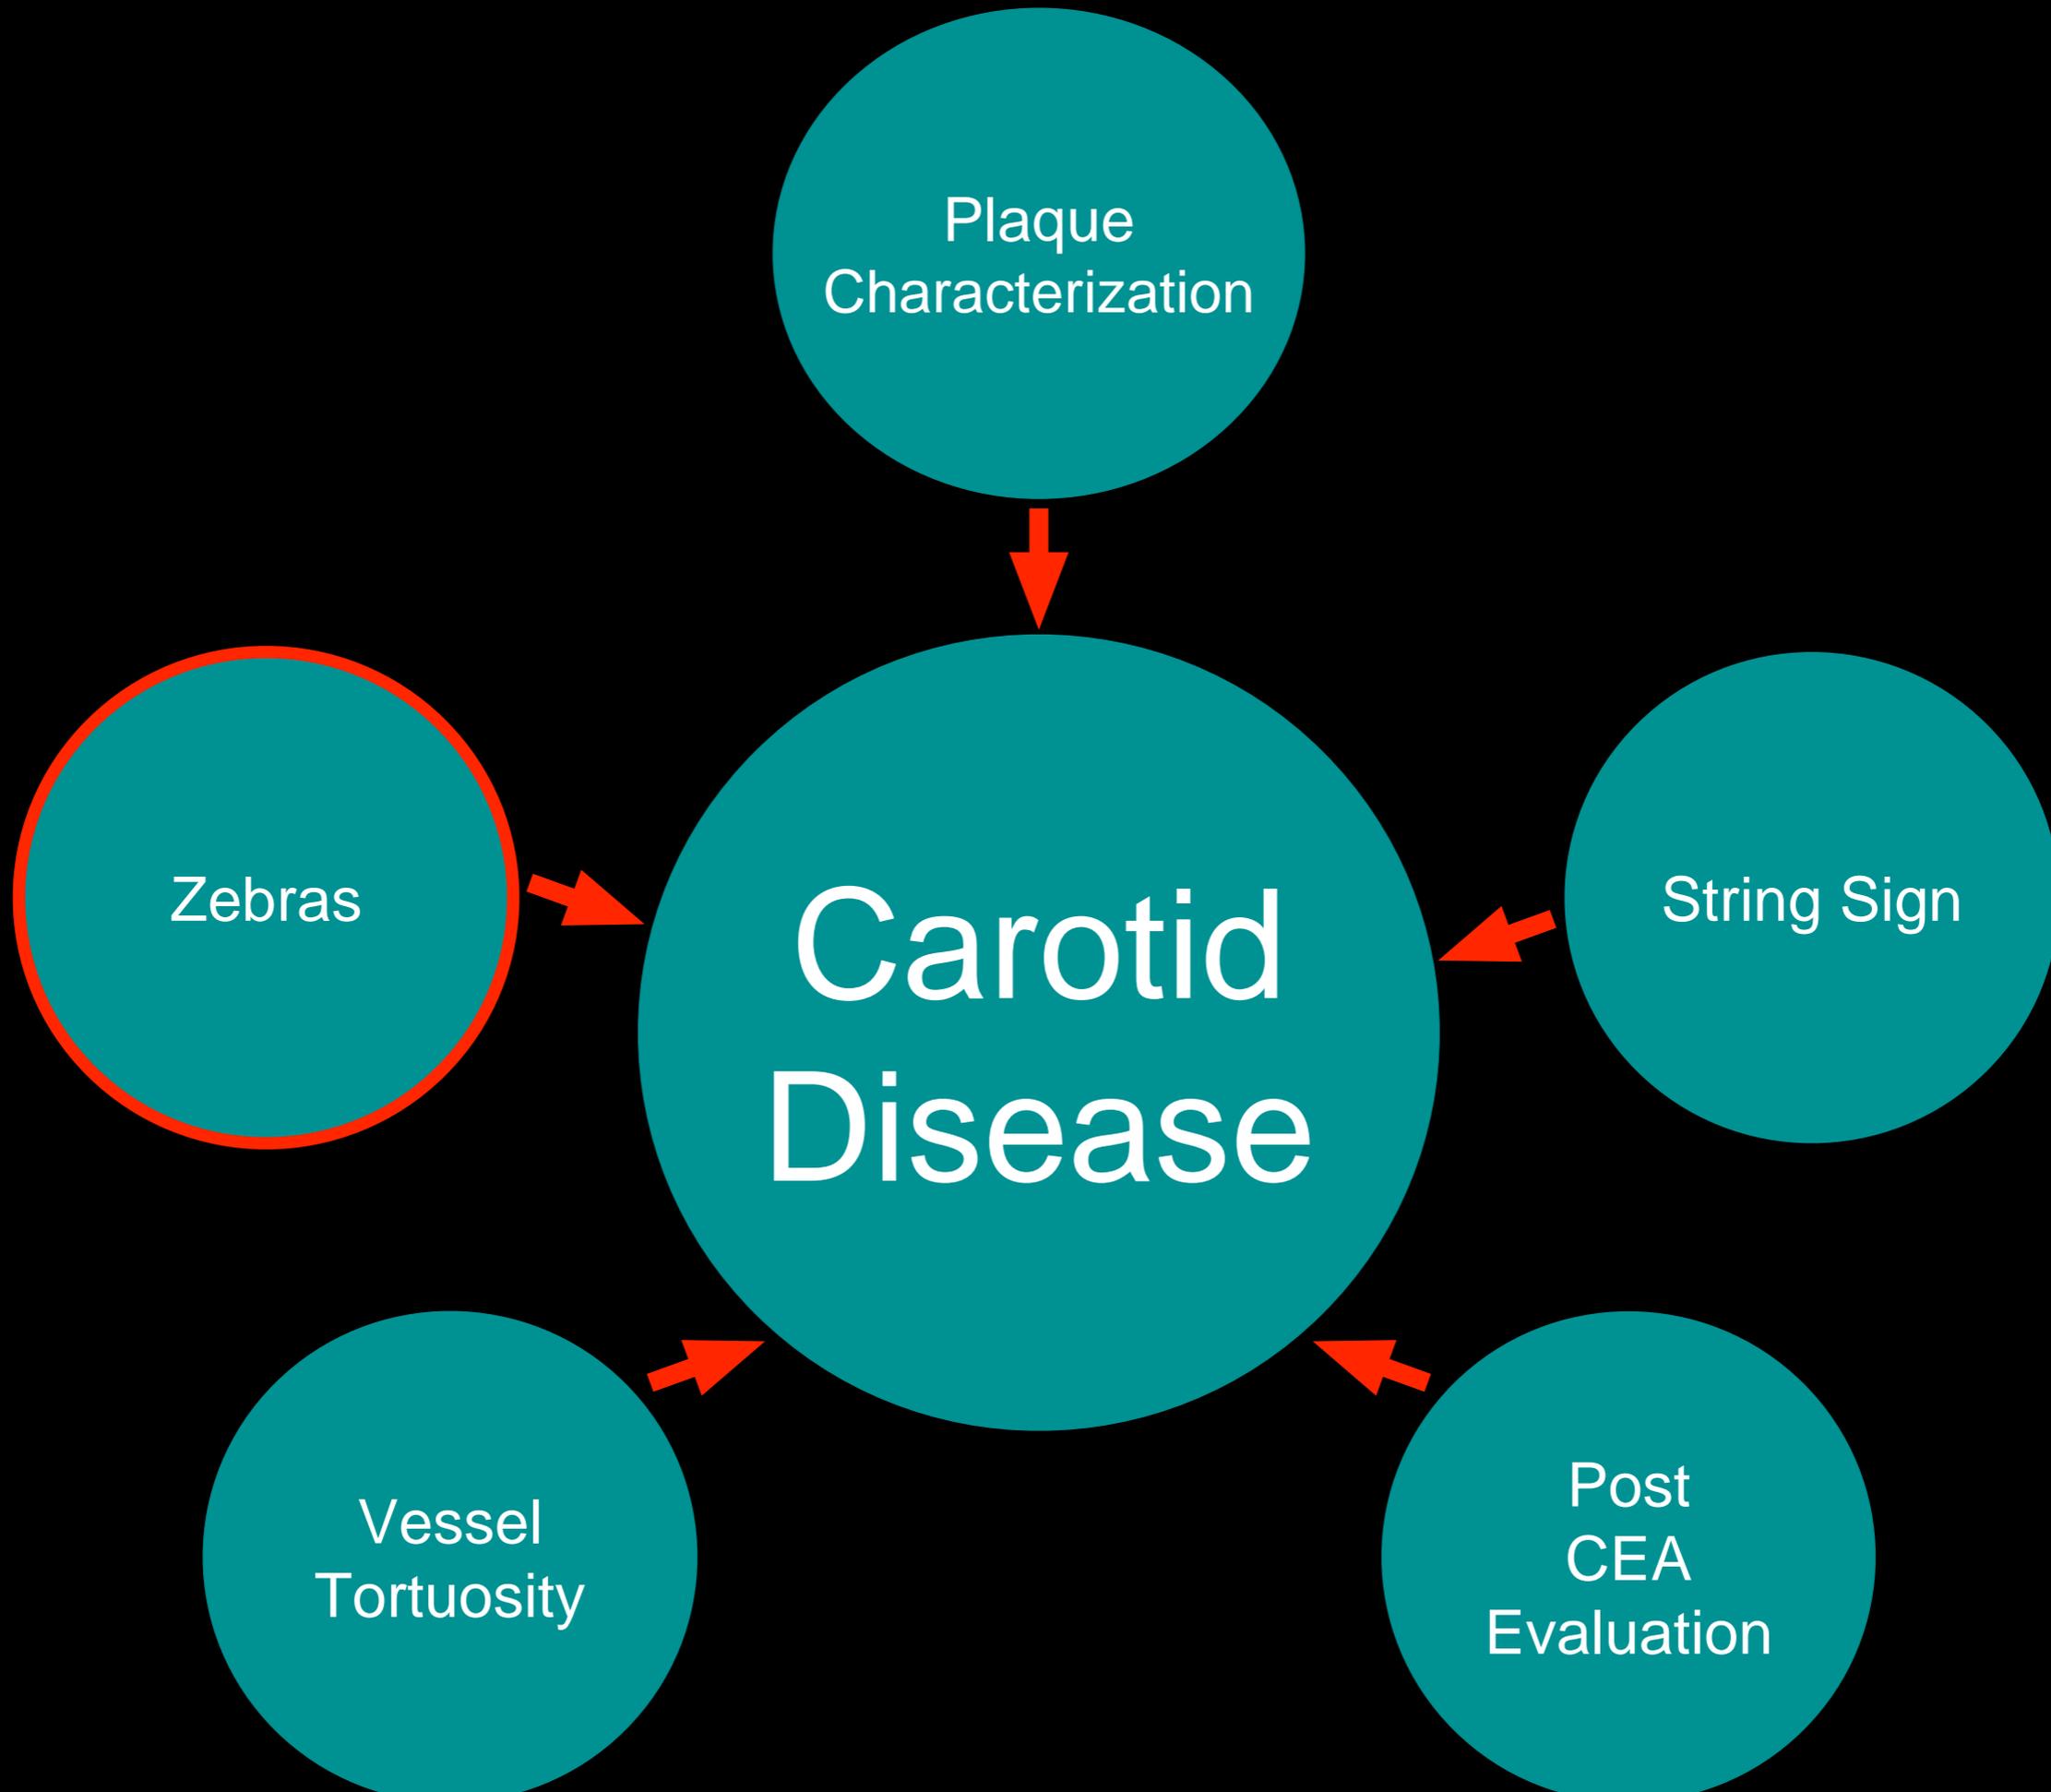

ICA Tortuosity

S-Shaped Curve

Not specific to FMD, though when noted on CDU < 70 YO -> high suspicion for the presence of FMD

Takayasu's Arteritis

Diffuse concentric heterogeneous thickening of the intima and media of the CCA

Appearance of a stuffed macaroni: "Macaroni Sign"

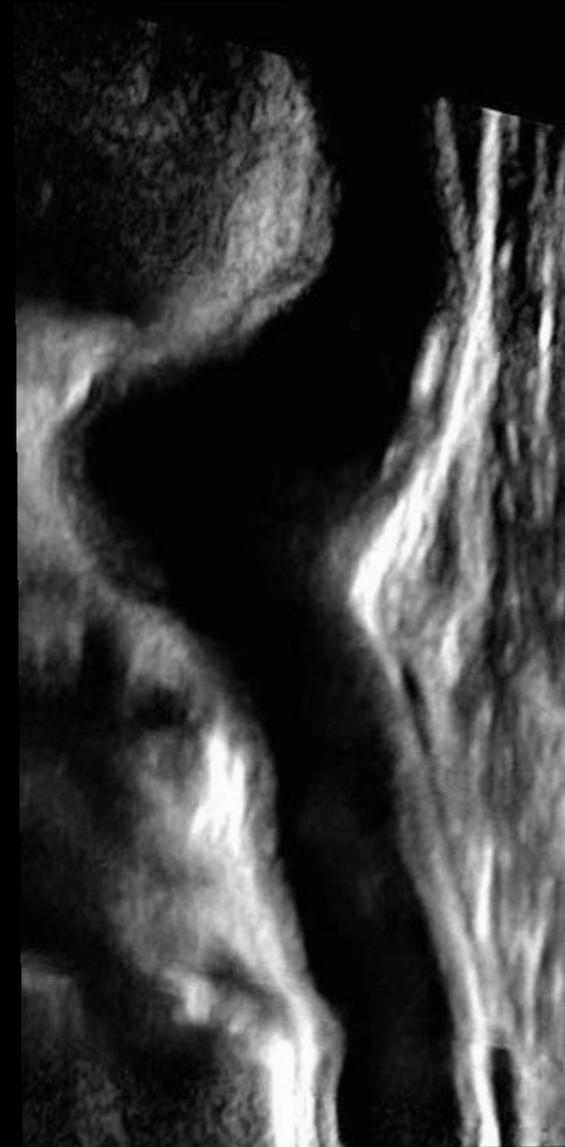

Aortitis - Circulation by HL Gornik- 2008

Maeda H, Handa N et al. Carotid lesions detected by B-mode ultrasonography in Takayasu's arteritis: "Macaroni sign" as an indicator of the disease. *Ultrasound in Medicine & Biology*, Volume 17, Issue 7, 1991

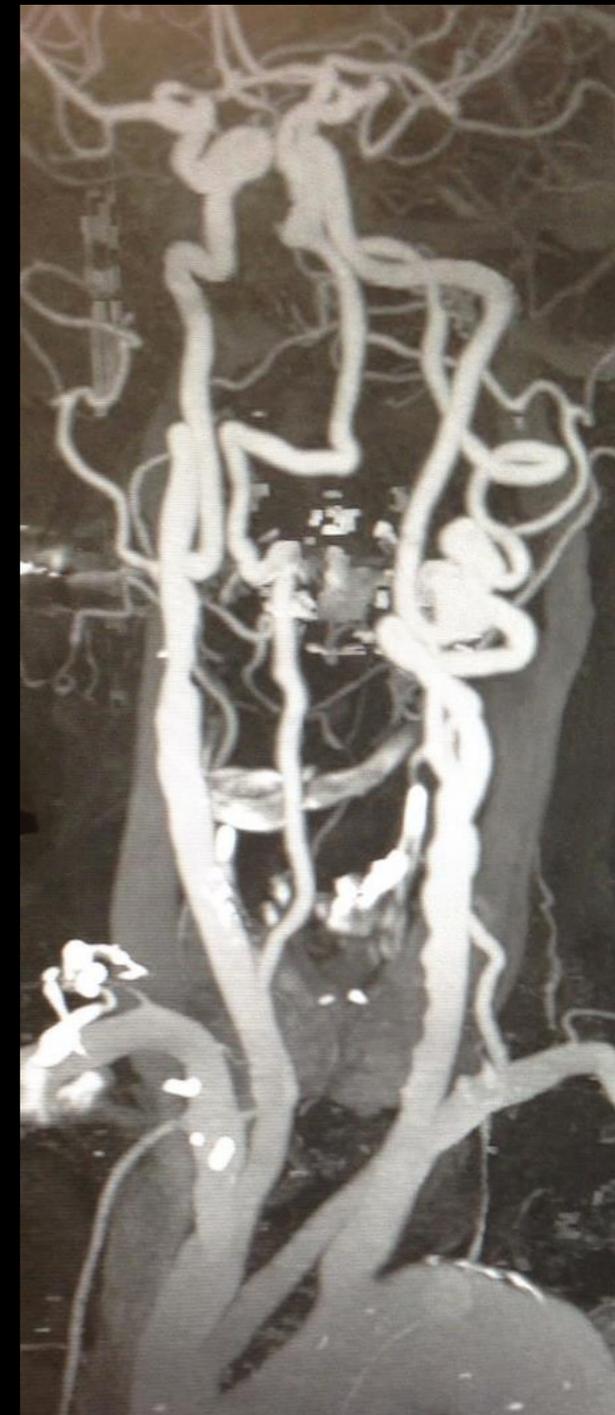

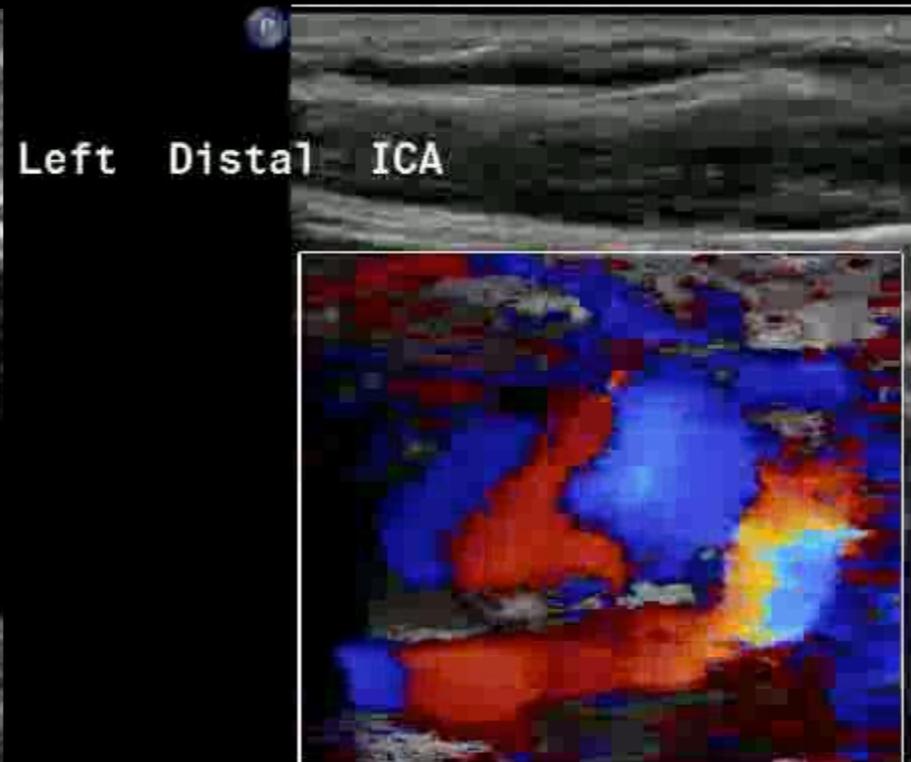

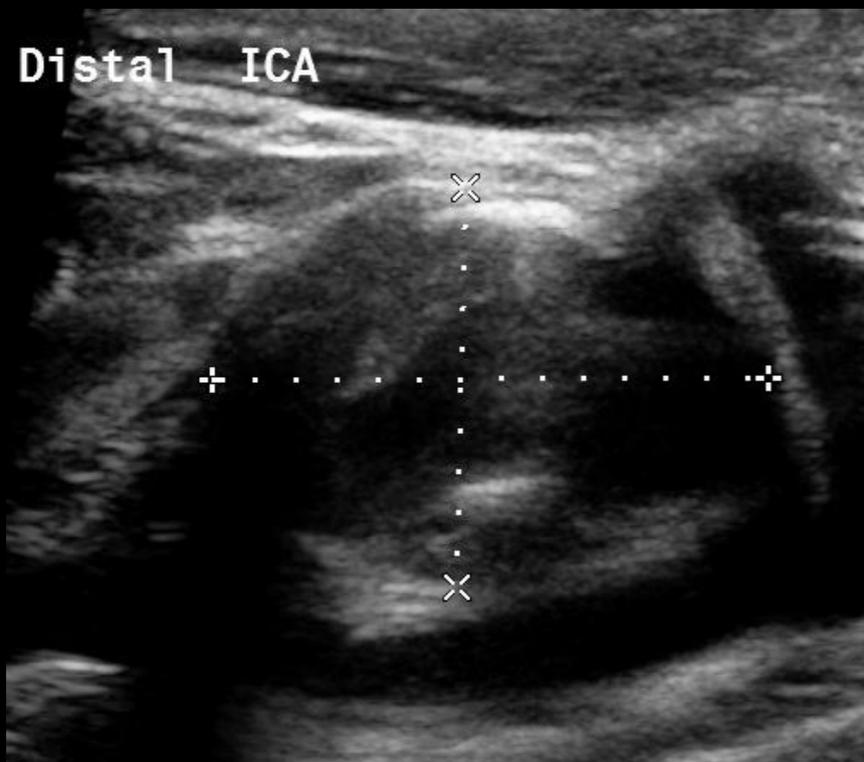

Carotid Artery Aneurysm

- Defined as:
Bulb dilatation $> 200\%$ of the diameter of the ICA or 150% of the diameter of the CCA
- Epidemiology:
Rare $< 1\%$ of all carotid pathologies
- Male:female=2:1, Age >60

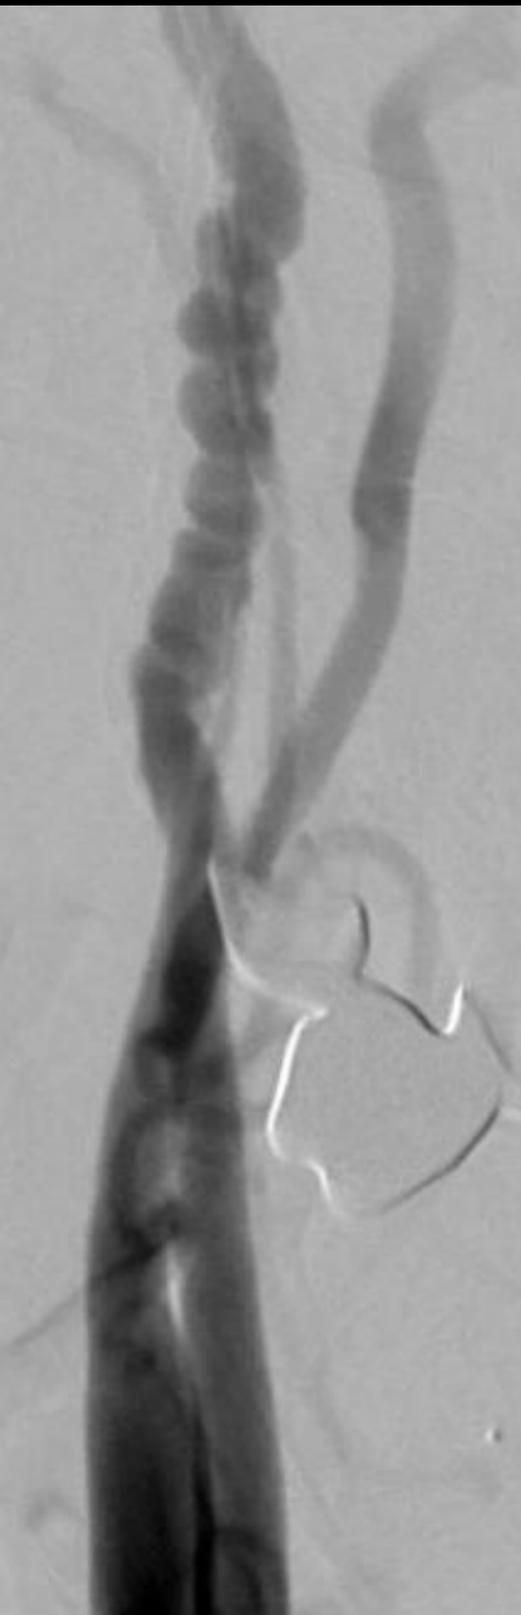

Carotid Artery Aneurysm

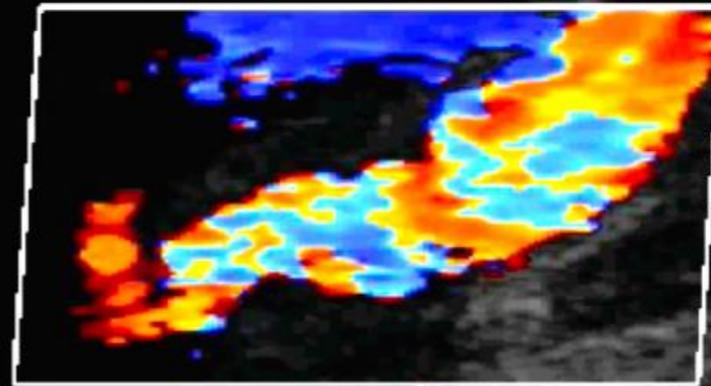

- Clinical Presentation: Horner's syndrome, pulsatile mass, neurologic symptoms, cranial nerve dysfunction, dysphagia, hemorrhage, and rupture
- Duplex characteristics: saccular dilation with mural thrombus measuring 2 x 2.5 cm

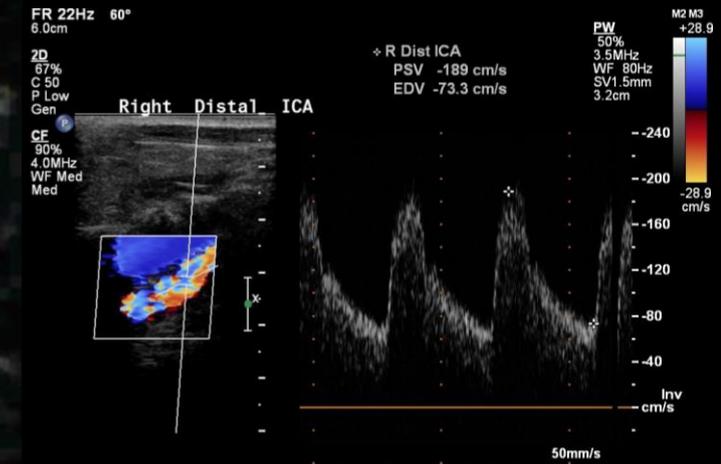

Carotid FMD

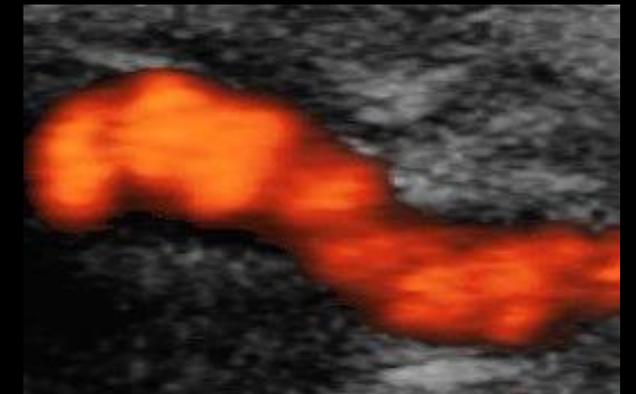

Gray Scale

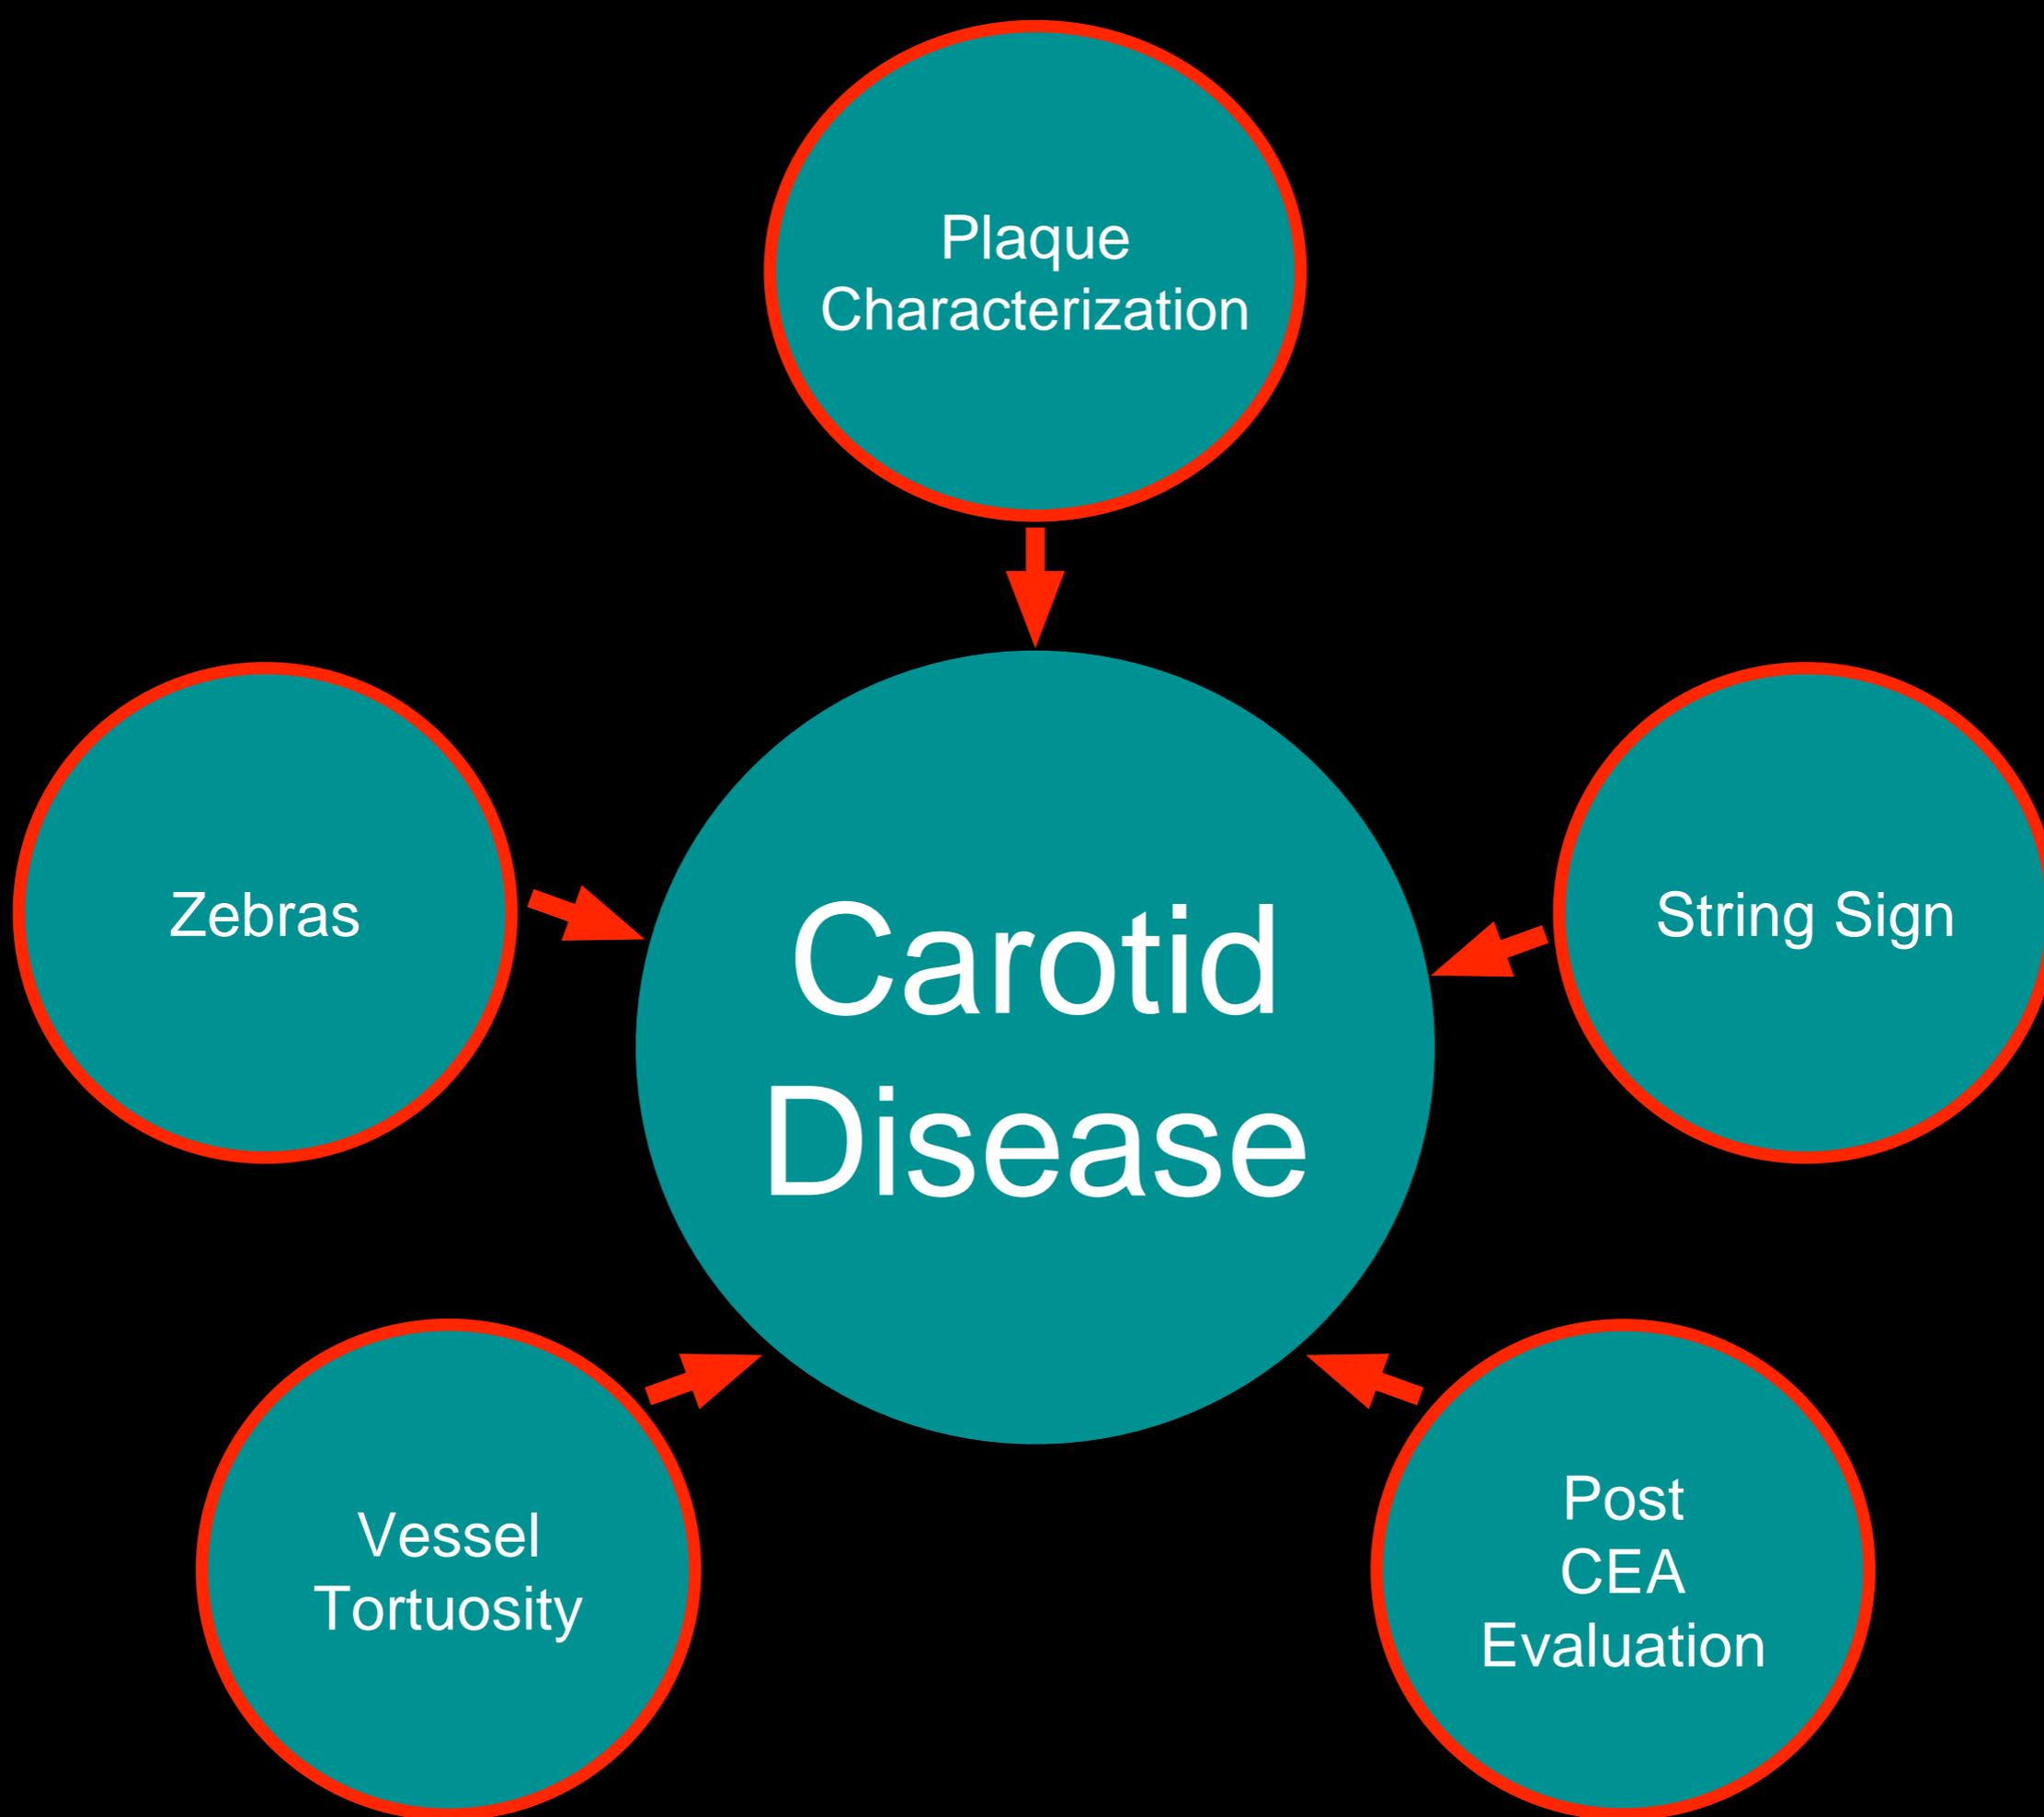

Color Flow

Spectral Doppler

Mid and Distal ICA FMD Power Doppler
